Release Information

For SRX5400, SRX5600, and SRX5800 devices, command introduced in Junos OS Release 9.6. For SRX5400 devices, the command is introduced in Junos OS Release 12.1X46-D20. For SRX300, SRX320, SRX340, and SRX345 devices, command introduced in Junos OS Release 15.1X49-D40. For SRX1500

devices, command introduced in Junos OS Release 15.1X49-D50. For SRX380 devices, command introduced in Junos OS Release 20.1R1.

Starting with Junos OS Release 15.1X49-D80, SRX4100 and SRX4200 devices support ISSU.

Starting with Junos OS Release 17.4R1, SRX4600 devices support ISSU.

SRX300 Series devices and vSRX Virtual Firewall do not support ISSU.

For SRX1500, SRX4100, SRX4200, SRX4600, SRX5400, SRX5600, and SRX5800, the `status` option is introduced in Junos OS Release 20.4R1.

RELATED DOCUMENTATION

request system software rollback (SRX Series)

request system software in-service-upgrade (MX Series 5G Universal Routing Platforms and EX9200 Switches)

IN THIS SECTION

Syntax

```
request system software in-service-upgrade package-name
<no-copy>
<no-old-master-upgrade>
```

```
<reboot>
<unlink>
```

Description

Perform a unified in-service software upgrade (unified ISSU). Unified ISSU enables you to upgrade from one Junos OS release to another with no disruption on the control plane and with minimal disruption of traffic. Unified ISSU is supported only by dual Routing Engine platforms. In addition, graceful Routing Engine switchover (GRES) and nonstop active routing (NSR) must be enabled.

Options

package-name

Location from which the software package or bundle is to be installed. For example:

- **/var/tmp/*package-name***— For a software package or bundle that is being installed from a local directory on the router.
- ***protocol://hostname/pathname/package-name***—For a software package or bundle that is to be downloaded and installed from a remote location. Replace ***protocol*** with one of the following:
  - **ftp**—File Transfer Protocol
  - **http**—Hypertext Transfer Protocol
  - **scp**—Secure copy (available only for Canada and U.S. version)

no-copy

(Optional) When the `no-copy` option is included, copies of package files are not saved on the Packet Forwarding Engine.

The `no-copy` option is not available for an MX Series Virtual Chassis or an EX9200 Virtual Chassis.

no-old-master-upgrade

(Optional) When the `no-old-master-upgrade` option is included, after the backup Routing Engine is rebooted with the new software package and a switchover occurs to make it the new primary Routing Engine, the former primary (new backup) Routing Engine is not upgraded to the new software. In this case, you must manually upgrade the former primary (new backup) Routing Engine. If you do not include the `no-old-master-upgrade` option, the system automatically upgrades the former primary Routing Engine.

The `no-old-master-upgrade` option is not available for an MX Series Virtual Chassis or an EX9200 Virtual Chassis.

reboot (Optional) When the `reboot` option is included, the former primary (new backup) Routing Engine is automatically rebooted after being upgraded to the new software. When the `reboot` option is not included, you must manually reboot the former primary (new backup) Routing Engine using the `request system reboot` command.

The `reboot` option is accepted but ignored for an MX Series Virtual Chassis or an EX9200 Virtual Chassis. A unified ISSU in an MX Series Virtual Chassis or EX9200 Virtual Chassis always reboots all Routing Engines in the member routers or switches.

unlink (Optional) When the `unlink` option is included, the package is removed from **/var/home** whether the installation is successful or unsuccessful.

The `unlink` option is not available for an MX Series Virtual Chassis or an EX9200 Virtual Chassis.

Additional Information

The following conditions apply to unified ISSUs:

- Unified ISSUs are supported on MX Series 5G Universal Routing Platforms and EX9200 switches.
- Unsupported PICs (on EX9200, PICs are known as “line cards”) are restarted during a unified ISSU. For information about supported PICs, see the Junos OS High Availability User Guide. For information about supported EX9200 line cards, see *Unified ISSU System Requirements*.
- Unsupported protocols will experience packet loss during a unified ISSU. For information about supported protocols, see the Junos OS High Availability User Guide or, for EX9200, see *Unified ISSU System Requirements*.
- During a unified ISSU, you cannot bring any PICs online or offline.

For more information, see the Junos OS High Availability User Guide.

Required Privilege Level

view

Output Fields

When you enter this command, you are provided feedback about the status of your request.

Sample Output

request system software in-service-upgrade reboot

```
{master}
user@host> request system software in-service-upgrade /var/tmp/jinstall-11.2B2.1-domestic-
signed.tgz reboot

request system software nonstop-upgrade (QFabric Systems)

IN THIS SECTION

- Syntax | 15312
- Description | 15312
- Options | 15312
- Required Privilege Level | 15313
- Output Fields | 15313
- Sample Output | 15313
- Release Information | 15319

Syntax

```
request system  software nonstop-upgrade package-name
<fabric >
<director-group>
<node-group name>
```

Description

Nonstop software upgrade enables you to upgrade a QFabric system with minimal packet loss and maximum uptime. You should upgrade the devices in the following order: Director group, fabric controls and Interconnect devices, and network and server Node groups.

> **NOTE**: Before you perform a nonstop software upgrade, contact JTAC to perform a pre-upgrade health check on the QFabric system.

Options

package-name Location from which the software is to be installed. For example:

- ***protocol://hostname/pathname/package-name***—For a software package or bundle that is to be downloaded and installed from a remote location. Replace ***protocol*** with one of the following:
  - **ftp**—File Transfer Protocol.
    Use **ftp://*hostname/pathname/package-name***. To specify authentication credentials, use **ftp://<*username*>:<*password*>@*hostname/pathname/package-name***. To have the system prompt you for the password, specify **prompt** in place of the password. If a password is required, and you do not specify the password or **prompt**, an error message is displayed.
  - **http**—Hypertext Transfer Protocol.
    Use **http://*hostname/pathname/package-name***. To specify authentication credentials, use **http://<*username*>:<*password*>@*hostname/pathname/package-name***. If a password is required and you omit it, you are prompted for it.
  - **scp**—Secure copy (available only for Canada and U.S. version).

Use **scp://** ***hostname/ pathname/ package-name***. To specify authentication credentials, use **scp://<*username*>:<*password*>@*hostname/ pathname/ package-name***.

> **NOTE:**
>
> - The ***pathname*** in the protocol is the relative path to the user's home directory on the remote system and not the root directory.

director-group Install software package on the Director group and Fabric managers.

fabric Install software package on the Interconnect devices and Fabric controls.

node-group *name* Install software package on the redundant server Node group, server Node group, or network Node group.

Required Privilege Level

maintenance

Output Fields

When you enter this command, you are provided feedback on the status of your request.

Sample Output

request system software nonstop-upgrade director-group

```
user@qfabric> request system software nonstop-upgrade director-group jinstall-qfabric-12.2X50-D10.3.rpm

Syntax

```
request system software nonstop-upgrade (package-name | set [package-name package-name])
<force-host>
<no-copy>
<no-old-master-upgrade>
<reboot >
<unlink>
```

Description

Perform a nonstop software upgrade (NSSU) on a switch with redundant Routing Engines or on a Virtual Chassis or Virtual Chassis Fabric (VCF). The behavior of this command depends on the type of switch, Virtual Chassis, or VCF where you run it, as follows:

- When you run this command on any of the following Virtual Chassis or VCF configurations, NSSU upgrades all members of the Virtual Chassis:
  - EX3300, EX3400, EX4200, EX4300,EX4400, EX4500, EX4550, EX4600, or EX4650-48Y Virtual Chassis
  - Mixed Virtual Chassis composed of any combination of EX4200, EX4500, and EX4550 switches, or EX4300 and EX4600 switches
  - QFX3500 and QFX3600 Virtual Chassis
  - QFX5100 Virtual Chassis
  - QFX5120-48Y, QFX5120-48T or QFX5120-32C Virtual Chassis
  - Fixed configuration of switches in a VCF (QFX3500/QFX3600 and QFX5100 switches)
  - Mixed VCF composed of any combination of QFX3500/QFX3600, QFX5100, and EX4300 switches

The original Virtual Chassis or VCF backup becomes the primary. The new primary automatically upgrades and reboots the original primary, which then rejoins the Virtual Chassis or VCF as the backup.

- When you run this command on an EX6200 or EX8200 switch, NSSU upgrades both the backup and primary Routing Engines. The original backup Routing Engine becomes the new primary at the end of the upgrade.
  - On an EX6200 switch, NSSU automatically reboots the original primary Routing Engine.
  - On an EX8200 switch, NSSU does not automatically reboot the original primary Routing Engine unless you specify the `reboot` option.
- When you run this command on an EX8200 Virtual Chassis, NSSU upgrades all primary and backup Routing Engines in the Virtual Chassis, including the external Routing Engines. The original backup Routing Engines become the new primary Routing Engines. NSSU does not automatically reboot the original primary Routing Engines unless you specify the `reboot` option.

This command has the following requirements:

- All Virtual Chassis members, VCF members, and all Routing Engines must be running the same Junos OS release.
- You must enable Graceful Routing Engine switchover (GRES)..
- You must enable Nonstop active routing (NSR).

> **NOTE**: Although not required, we recommend you also enable nonstop bridging (NSB). NSB ensures that all NSB-supported Layer 2 protocols operate seamlessly during the Routing Engine switchover during NSSU. See Configuring Nonstop Bridging on EX Series Switches (CLI Procedure).

- You must run the command from the primary Routing Engine on a standalone switch or from the primary on a Virtual Chassis.
- For minimal traffic disruption, you must define link aggregation groups (LAGs) such that the member links reside on different Virtual Chassis or VCF member switches (or on different line cards for EX6200 and EX8200 switches and EX8200 Virtual Chassis).
- For all Virtual Chassis (except EX8200 Virtual Chassis):
  - The Virtual Chassis members must be connected in a ring topology. A ring topology prevents the Virtual Chassis from splitting during an NSSU.

- The Virtual Chassis primary and backup must be adjacent to each other in the ring topology. With adjacent placement, the primary and backup are always in sync while the switches in line-card roles are rebooting.
- The Virtual Chassis must be preprovisioned so the line-card role is explicitly assigned to member switches acting in a line-card role. During an NSSU, the primary and backup member switches must maintain their Routing Engine roles (although the primary role switches to the backup), and the remaining switches must maintain their line-card roles.
- In a two-member Virtual Chassis, you must configure `no-split-detection` so the Virtual Chassis doesn't split during NSSU.

- For Virtual Chassis Fabric:
  - You can only have two members preprovisioned in the Routing Engine role. If more than two Routing Engines are configured, NSSU issues a warning message and the NSSU process stops.
  - The VCF members should be connected in a spine and leaf topology. A spine and leaf topology prevents the VCF from splitting during NSSU. Each leaf device must be connected to both spine devices.
  - The VCF must be preprovisioned so that the line-card role has been explicitly assigned to member switches acting in a line-card role, and likewise the Routing Engine role has been explicitly assigned to the member switches acting in a Routing Engine role. During an NSSU, the primary and backup member switches must maintain their Routing Engine roles (although the primary role switches to the backup), and the remaining switches must maintain their line-card roles.
  - You must configure `no-split-detection` in a two-member VCF so the VCF does not split during NSSU.

Options

package-name

Location of the software package or bundle to be installed. For example:

- `/var/tmp/`*`package-name`*—For a software package or bundle installed from a local directory on the switch.
- *`protocol`*`://`*`hostname`*`/`*`pathname`*`/`*`package-name`*—For a software package or bundle downloaded and installed from a remote location. Replace *`protocol`* with one of the following:
  - `ftp`—File Transfer Protocol.
    Use `ftp://`*`hostname`*`/`*`pathname`*`/`*`package-name`*.

To specify authentication credentials, use `ftp://<username>:<password>@hostname/pathname/package-name`.
To have the system prompt you for the password, specify `prompt` in place of the password.
The command displays an error message If a password is required and you do not specify the password or `prompt`.

- `http`—Hypertext Transfer Protocol.
  Use `http://hostname/pathname/package-name`.
  To specify authentication credentials, use `http://<username>:<password>@hostname/pathname/package-name`.
  The command prompts you for a password if one is required and you didn't include it.

- `scp`—Secure copy (available only for Canada and U.S. version).
  Use `scp://hostname/pathname/package-name`.
  To specify authentication credentials, use `scp://<username>:<password>@hostname/pathname/package-name`.

> **NOTE**: The *pathname* in the protocol is the relative path to the user home directory on the remote system and not the root directory.

set [*package-name package-name*]
(Mixed Virtual Chassis only) Locations of the different installation packages required by the different types of member switches. These packages must be for the same Junos OS release. See this command's *package-name* option for information about how to specify the installation packages.

force-host
(Optional) Force adding the host software package or bundle (and ignore warnings) on EX4650, QFX5100, or QFX5120 devices.

no-copy
(Optional) Install a software package or bundle, but do not save copies of the package or bundle files.

no-old-master-upgrade
(Optional) (EX8200 switches only) Upgrade the backup Routing Engine only. After the upgrade completes, the original primary Routing Engine becomes the backup Routing Engine and continues running the previous software version.

reboot
(Optional) (EX8200 switches and EX8200 Virtual Chassis only) When you include the `reboot` option, NSSU automatically reboots the original primary (new backup) Routing Engine after being upgraded to the new software. When you omit the `reboot` option, you must manually reboot the original primary (new backup) Routing Engine using the `request system reboot` command.

> **NOTE**: If you do not use the `reboot` option on an EX8200 Virtual Chassis, you must establish a connection to the console port on the Switch Fabric and Routing Engine (SRE) module or Routing Engine (RE) module to manually reboot the backup Routing Engines.

unlink (Optional) Remove the software package after a successful upgrade.

Required Privilege Level

maintenance

Output Fields

This command reports feedback on the status of the request. Some functions are shared between NSSU and the in-service software upgrade (ISSU) feature, so you might see what appear to be ISSU messages as well as NSSU messages in the output from this command.

Sample Output

request system software nonstop-upgrade (EX4200 Virtual Chassis)

- Release Information | 15337

Syntax

```
request system software recovery-package ( add package-name | delete package-name | extract (ex-
xre200-package | ex-8200-package) package-name)
<backup>
<master>
```

Description

Add, remove, or extract a software recovery package for the EX8200 switch or the XRE200 External Routing Engine in an EX8200 Virtual Chassis.

Use this command to load a software recovery package onto the USB flash drive of the external Routing Engine and then extract it to the recovery partition of the external Routing Engine—so that it is available for use during a software recovery installation. During a software recovery installation procedure, you are prompted to select which software recovery package to use for the recovery.

> **NOTE**: This command is available only on the external Routing Engine.

If you do not have the desired software recovery package already installed in the recovery partition of the external Routing Engine, download the software package from the Internet.

Options

An EX8200 Virtual Chassis supports up to two external Routing Engines for the purpose of external Routing Engine redundancy. If you have configured two external Routing Engines, one functions as the primary external Routing Engine and the other functions as the backup. If you have not configured two external Routing Engines, the `backup` and `master` options are not relevant.

add *package-name* backup | master

Load the EX8200 software recovery package or the XRE200 software recovery package onto the USB flash drive of the external Routing Engine.

> **NOTE**: You can have up to five software recovery packages loaded in the USB flash drive.

- ***package-name***—path name of the software recovery package.
- **backup**—(Optional) Load the specified package onto the USB flash drive of the backup external Routing Engine.

- **master**—(Optional) Load the specified package onto the USB flash drive of the primary external Routing Engine.

delete *package-name* backup | master

Delete the EX8200 software recovery package or the XRE200 software recovery package from the USB drive of the external Routing Engine.

- ***package-name***—Path name of the software package.
- **backup**—(Optional) Delete the specified package from the USB flash drive of the backup external Routing Engine.
- **master**—(Optional) Delete the specified package from the USB flash drive of the primary external Routing Engine.

extract (ex-xre200-package | ex-8200-package) *package-name* backup | master

Extract either the XRE200 software recovery package or the EX8200 software recovery package from the USB flash drive of the external Routing Engine and put it into the recovery partition of the external Routing Engine.

- ***package-name***—Path name of the software recovery package.
- **backup**—(Optional) Extract the specified package from the USB flash drive to the recovery partition of the backup external Routing Engine.
- **master**—(Optional) Extract the specified package from the USB flash drive to the recovery partition of the primary external Routing Engine.

request system software restore-point

IN THIS SECTION

- Syntax | 15338
- Description | 15338
- Required Privilege Level | 15338
- Sample Output | 15338
- Release Information | 15340

Syntax

```
request system software restore-point
```

Description

Use this command to create a restore-point. A restore-point is a snapshot of the software on the QFabric system as well as the configuration that can be rolled back to in cases where a software upgrade or configuration changes have made the QFabric system unstable or inoperable.

Required Privilege Level

configure

Sample Output

request system software restore-point

```
root@qfabric> request system software restore-point
Checking if director-device upgrade is currently in progress.

- Output Fields | 15343
- Sample Output | 15343
- Release Information | 15344

Syntax

```
request system software rollback
```

Syntax (EX Series Switches)

```
request system software rollback
<all-members>
<local>
<member member-id>
<reboot>
```

Syntax (MX Series Router)

```
request system software rollback
<all-members>
<device-alias alias-name>
<local>
<member member-id
<reboot>
<satellite slot-id>
<upgrade-group [all |upgrade-group-name]>
```

Syntax (SRX Series Firewalls)

```
request system software rollback <node-id>
```

Description

Use this command to revert to the last successfully installed package before the `request system software (add | delete)` command. It uses the copy stored in the **/var/sw/pkg** directory.

Additional Information

- On Junos Fusion, the `request system software rollback` command can be used to roll back the version of satellite software associated with a satellite software upgrade group. Rolling back the version of satellite software associated with a satellite software upgrade group triggers a satellite software upgrade.
- On SRX Series Firewalls with dual root systems, when `request system software rollback` is run, the system switches to the alternate root. Each root can have a different version of Junos OS. Roll back takes each root back to the previously installed image.
- For SRX300, SRX320, SRX340, SRX345, and SRX380 firewalls, you cannot use the `request system rollback` command to roll back from Junos OS Release 24.4R1 to either Junos OS Release 23.4R2-S3 or to Release 24.2R2. Instead, you must treat the rollback as a downgrade, and use the `request system software add` *`package-name`* `no-validate reboot` command instead.
- On QFX3500 and QFX3600 devices in a mixed Virtual Chassis, when the `request system software rollback` command is issued, the system does not rollback to the image stored in the alternate partition.
- On QFX5100 switches, the `reboot` option has been removed. To reboot the switch after a software rollback, issue the `request system reboot` command as a separate, secondary command.

Options

all-members (EX4200 switches and MX Series routers only) (Optional) Attempt to roll back to the previous set of packages on all members of the Virtual Chassis configuration.

device-alias *alias-name* (Junos Fusion only) (Optional) Rollback the satellite software package onto the specified satellite device using the satellite devices FPC slot identifier.

local (EX4200 switches and MX Series routers only) (Optional) Attempt to roll back to the previous set of packages on the local Virtual Chassis member.

member *member-id*	(EX4200 switches and MX Series routers only) (Optional) Attempt to roll back to the previous set of packages on the specified member of the Virtual Chassis configuration. For EX4200 switches, replace *member-id* with a value from 0 through 9. For an MX Series Virtual Chassis, replace *member-id* with a value of 0 or 1.
node-id	(SRX Series Firewalls only) Identification number of the chassis cluster node. It can be 0 or 1.
none	Revert to the last known good state before the most recent `request system software (add | delete)` command.
reboot	(Optional) The system reboots automatically to complete the rollback.
satellite *slot-id*	(Junos Fusion only) (Optional) Roll back the satellite software package onto the specified satellite device using the satellite devices FPC slot identifier.
upgrade-group [all |*upgrade-group-name***]**	(Junos Fusion only) Roll back the satellite software image associated with the specified satellite software upgrade group, or for all satellite software upgrade groups in the Junos Fusion when `all` is entered.

request system software rollback (Junos OS Evolved)

IN THIS SECTION

- Syntax | 15345
- Description | 15346
- Options | 15346
- Required Privilege Level | 15346
- Output Fields | 15346
- Sample Output | 15347
- Release Information | 15348

Syntax

```
request system software rollback reboot
<no-validate>
<package-name version>
<with-old-snapshot-config>
```

Description

Use this command to revert to the last successfully installed package before the last-issued `request system software (add | delete)` command. By default, once the software is rolled back, the device uses the current configuration file. You can use this command on either Routing Engine in a dual-Routing Engine system.

On Junos OS Evolved, the `reboot` option is required in order to complete the rollback.

Options

package-name *version*
Select any installed version for the rollback. The `request system software rollback` operational mode command uses the version instead of the package-name. You can see the available versions by using the `show system software list` operational mode command. If you do not specify the version, the system rolls back to the default rollback version (the one with the '<' before it on the `show system software list` command output). You can specify any previous Junos OS Evolved release as long as it is neither the one that is currently running nor the rollback version.

no-validate
Do not check compatibility with the current configuration.

Default: validate

reboot
(Optional) Reboot to complete the rollback. If you do not specify the `reboot` option, then when this command completes, you need to issue the `request system reboot` operational mode command to reboot the system to finish the rollback process.

with-old-snapshot-config
(Optional) Rolls back the system to the specified version with the old snapshot of the configuration used in that version. Otherwise, the rollback, by default, takes the current configuration.

Required Privilege Level

maintenance

Output Fields

When you enter this command, the system provides feedback on the status of your request.

Sample Output

request system software rollback with-old-snapshot-config

```

request system software sync

IN THIS SECTION

- Syntax | 15349
- Description | 15349
- Options | 15349
- Additional Information | 15350

- Required Privilege Level | 15351
- Sample Output | 15351
- Release Information | 15352

Syntax

```
request system software sync (current | rollback | all-versions)
```

Description

Use this command on the primary Routing Engine of a system to synchronize the software and configurations from the primary Routing Engine to the other nodes and reboot the other nodes. The configurations are synchronized even if the images are identical. If specified on the backup Routing Engine, the command fails.

NOTE: The `request system software sync` command is only supported on PTX Series and QFX Series devices that have two Routing Engines.

Options

`current | rollback | all-versions`

Specify which software version (current, rollback, or all versions) to sync to the other node:

- For the `current` option, the system syncs the current version from the primary Routing Engine to the other node and reboots the other node with that version. If the current version on the primary Routing Engine of the system matches the version on the other node of the system, the command fails.
- For the `rollback` option, the system synchronizes the rollback version to the other node. If the rollback version on the primary Routing Engine of the system matches the rollback version on the other node, the command fails.
- For the `all-versions` option, the system synchronizes all software versions and configurations from the primary Routing Engine to the other node and reboots the other node if there's a mismatch between current versions.

Additional Information

For the `all-versions` option, the synchronization proceeds as follows:

1. All versions are deleted on the other node, except for the current version.
2. The current and rollback images and configurations are copied from the primary Routing Engine to the other node. Even if the software versions match, the configuration is copied and the software proceeds to the next image.
3. Any other versions and configurations are copied from the primary Routing Engine to the other node.
4. If the current version on the other node is not the same as current on the primary Routing Engine, then the other node is rebooted after warning the user.

The `request system software sync all-versions` command is successful if the first two steps of the synchronization are successful. If step 3 fails, a warning message is displayed. To make the versions match, you can delete the extra versions using the `request system software delete` operational mode command.

To see what the software versions are available on the device, use the `show system software list` command.

If an Routing Engine that has a different software version is inserted into the system, the Routing Engine is kept outside the system and a software mismatch alarm is generated, which specifies the Routing Engine name and the version of software on that Routing Engine, similar to the following: `Software Version Mismatch on re1:junos-evo-install-ptx-x86-64-20.4R2.6-EVO.` To clear this alarm, use the `request system software sync all-versions` command to synchronize the software. Once the new Routing Engine comes back up, it joins the system.

```
user@host-re0> show system alarms
2 alarms currently active
Alarm time               Class  Description
2021-04-19 16:02:26 PDT  Major  Re1 Node unreachable
2021-04-19 16:04:46 PDT  Major  Software Version Mismatch on re1:junos-evo-install-ptx-
x86-64-20.4R2.6-EVO
```

For the `current` option, before you switch control to a newly-inserted Routing Engine, ensure all images are synchronized to the newly-inserted Routing Engine by using the output from the `show system software list` operational mode command to compare the images installed on both Routing Engines and make sure they are the same. You must make sure that the system has finished synchronizing all of the images in the background before you switch control to the newly- inserted Routing Engine to ensure that the newly-inserted Routing Engine does not remove any images from the existing Routing Engine.

```

Description

(QFabric systems only) Save a copy of the current QFabric system configuration file and the current software package for recovery purposes. You can use these saved files to restore your QFabric system to full operation after a system failure or shutdown.

Options

none Copy the QFabric system software package and system configuration file to a Director group recovery directory.

> **NOTE**: If this command fails, insert a Juniper Networks software installation USB flash drive into the primary Director device and issue the `request system software format-qfabric-backup` command. For more details about this prerequisite procedure that is required before you can use the QFabric system backup and

recovery feature, see *Performing System Backup and Recovery for a QFabric System*.

usb-create Copy the QFabric system software package and system configuration file from the Director group recovery directory to a USB flash drive. When the files have been copied, you can use the USB flash drive to help your QFabric system recover from a failure condition.

> **NOTE**: You must issue the `request system software system-backup` command (which saves the files to the Director group) before you can issue the `request system software system-backup usb-create` command.

Required Privilege Level

maintenance

Output Fields

When you enter these commands, you are provided feedback on the status of your request.

Sample Output

request system software system-backup

```
user@qfabric> request system software system-backup

user@qfabric>
```

request system software system-backup usb-create

```
user@qfabric> request system software system-backup usb-create /dev/sdb
Issuing this command will overwrite the contents of the USB drive.
Continue? [yes,no] (no) yes

This operation will access the USB drive on 0281042010000013.
Are you sure you want to continue? [yes,no] (no) yes
```

```
Copying QFabric recovery media to /dev/sdb...
Successfully copied QFabric recovery media to /dev/sdb
```

Release Information

Command introduced in Junos OS Release 13.1.

Syntax

```
request system software validate in-service-upgrade package-name
<enhanced-mode>
```

Description

Perform a compatibility check to ensure that the software and hardware components and the configuration on the device support unified ISSU. The `request system software validate in-service-upgrade` command enables you to detect any compatibility issues before actually issuing the `request system software in-service-upgrade` command to initiate unified ISSU.

Options

package-name

Location from which the software package or bundle is to be installed. For example:

- `/var/tmp/`*`package-name`*—For a software package or bundle that is being installed from a local directory on the router.
- *`protocol`*`://`*`hostname`*`/`*`pathname`*`/`*`package-name`*—For a software package or bundle that is to be downloaded and installed from a remote location. Replace *`protocol`* with one of the following:
  - `ftp`—File Transfer Protocol
  - `http`—Hypertext Transfer Protocol
  - `scp`—Secure copy (available only for Canada and U.S. version)

enhanced-mode

(Optional) Checks for compatibility with enhanced mode—a mode of ISSU that eliminates packet loss during the unified ISSU process.

> **NOTE**: The enhanced mode option is available on MPC7E, MPC8E, and MPC9E line cards starting from Junos OS Release 20.1R1. Support for MPC11E line cards is provided from Junos OS Release 21.4R1 onwards.

Additional Information

Unified ISSU is not supported on every platform. For a list of supported platforms, see *Unified ISSU System Requirements*.

Required Privilege Level

view

Output Fields

When you enter this command, Junos OS displays the status of your request.

Sample Output

request system software validate in-service-upgrade

```

<member member-id>
<on (host host <username username> | routing-engine routing-engine)>
<set [package-name package-name]>
<upgrade-with-config>
<upgrade-with-config-format format>
```

Description

Use this command to validate candidate software against the current configuration of the router, the switch, or a remote host.

Options

lcc *number*

(TX Matrix routers and TX Matrix Plus routers only) (Optional) On a TX Matrix router, validate the software bundle or package on a specific T640 router (or line-card chassis) that is connected to the TX Matrix router. On a TX Matrix Plus router, validate the software bundle or package for a specific router that is connected to the TX Matrix Plus router.

Replace *number* with the following values depending on the LCC configuration:

- 0 through 3, when T640 routers are connected to a TX Matrix router in a routing matrix.
- 0 through 3, when T1600 routers are connected to a TX Matrix Plus router in a routing matrix.
- 0 through 7, when T1600 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.
- 0, 2, 4, or 6, when T4000 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.

on (host *host*<username *username*> | routing-engine *routing-engine*)

(Optional) Validate the software bundle or package by comparing it to the running configuration on a remote host or Routing Engine. Specify either a host, replacing *host* with the remote hostname, or a Routing Engine, replacing *routing-engine* with the Routing Engine name. If you specify a remote host, you can optionally provide the username to be used to log in to the remote host.

member *member-id*	(MX Series routers only) (Optional) Validate the software bundle or package on the specified member of the Virtual Chassis configuration. For an MX Series Virtual Chassis, replace *member-id* with a value of 0 or 1.
package-name	Name of the software bundle or package to test.
scc	(TX Matrix routers only) (Optional) Validate the software bundle or package for the TX Matrix router (or switch-card chassis).
set [*package-namepackage-name*]	(M Series, MX Series, T Series routers) (Optional) Install multiple software packages or software add-on packages at the same time.
sfc *number*	(TX Matrix Plus routers only) (Optional) Validate the software bundle or package for the TX Matrix Plus router.
upgrade-with-config	(Optional) Install one or more configuration files.
upgrade-with-config-format *format*	(Optional) Specify the configuration file fomat, `text` or `xml`. The default format is `text`. The `upgrade-with-config` and `upgrade-with-config-format` options are only available locally on the router or switch. In a routing matrix, the configuration is applied only to the local router and is not propagated to other routers. The options are validated during the validation process and applied to the router or switch during the upgrade process. If the upgrade process is successful, the options are removed from the configuration. If the upgrade process fails, the configuration file is renamed with the .failed suffix.

Additional Information

By default, when you issue the `request system software validate` command on a TX Matrix primary Routing Engine, all the T640 primary Routing Engines that are connected to it are validated. If you issue the same command on the TX Matrix backup Routing Engine, all the T640 backup Routing Engines that are connected to it are upgraded to the same version of software.

Likewise, if you issue the `request system software validate` command on a TX Matrix Plus primary Routing Engine, all the T1600 or T4000 primary Routing Engines that are connected to it are validated. If you issue the same command on a TX Matrix Plus backup Routing Engine, all the T1600 or T4000 backup Routing Engines that are connected to it are upgraded to the same version of software.

Release Information

Command introduced before Junos OS Release 7.4.

`sfc` option introduced for the TX Matrix Plus router in Junos OS Release 9.6.

`set [package-namepackage-name]` option added in Junos OS Release 12.2 for M Series, MX Series, T Series routers.

`upgrade-with-config` and `upgrade-with-config-format format` options added in Junos OS Release 12.3 for M Series routers, MX Series routers, and T Series routers.

`on (host host<username username> | routing-engine routing-engine)` option introduced in Junos OS Release 13.3, Junos OS Release 14.1, and Junos OS Release 15.1.

IN THIS SECTION

- Syntax | 15366
- Description | 15366
- Options | 15366
- Required Privilege Level | 15366
- Output Fields | 15366
- Sample Output | 15367

Release Information | 15367

Syntax

```
request system software validate package-name
<restart>
```

Description

Use this command to validate the candidate software package against the current configuration of the node. The configuration check does not change the current software or the file system.

You can use the `request system software validate` command before using the `request system software add restart` command to determine if you can upgrade to the new image with an application restart or with a reboot.

Options

package-name	Name of the software bundle or package to test.
restart	(Optional) Verify the new software configuration compatibility. When you issue the command with this option, the output lists those services that might be restarted.

Required Privilege Level

maintenance

Output Fields

When you enter this command, the system provides feedback on the status of your request.

request system software validate on (Junos OS with Upgraded FreeBSD)

IN THIS SECTION

- Syntax | 15368
- Description | 15368
- Options | 15368
- Additional Information | 15369
- Required Privilege Level | 15369
- Output Fields | 15369
- Sample Output | 15369
- Release Information | 15371

Syntax

```
request system software validate on
<host host-name [ username user-name ]>
<routing-engine (re0 | re1)>
```

Description

Use this command to validate the current configuration on a Routing Engine that is not running Junos OS with upgraded FreeBSD or a remote host.

Direct validation of a running configuration is not possible on a device running Junos OS with upgraded FreeBSD. Nevertheless, validation is an important step in the installation of an upgraded operating system. This command allows validation on a device that is not running Junos OS with upgraded FreeBSD.

Options

The specific options available are:

host *host-name* **[username** *user-name* **]**	Validate the current configuration on a remote host. The host-name is resolved through DNS. Optionally, you can supply a username to employ on the remote

host. If you omit the username option, the currently logged-in user-name is sent to the remote host.

routing-engine (re0 | re1) Validate the current configuration on another Routing Engine on the same device. The other Routing Engine cannot be running Junos OS with upgraded FreeBSD or the validation does not succeed.

Additional Information

If the authenticity of the remote host cannot be established, you are prompted to continue the validation or not. If you choose not to continue, the validation process does not take place.

Required Privilege Level

maintenance

Output Fields

When you enter this command, you are provided feedback on the status of your request.

Sample Output

request system software validate on host

```
user@host> request system software validate on host remote-validator
The authenticity of host 'remote-validator (192.168.164.174)' can't be established.
ECDSA key fingerprint is 73:d0:78:ce:8d:09:aa:92:4c:ce:45:52:1d:76:86:b5.
Are you sure you want to continue connecting (yes/no)? yes

Syntax

```
request system software validate-restart package-name
```

Description

Verify the new package against the current configuration to ensure that it supports unified in-service software upgrade (unified ISSU). The command output also indicates which applications can be upgraded by using an application-level restart or an in-service kernel warm restart. Use this command before you run `request system software add restart` to detect any compatibility issues before actually upgrading the software.

NOTE: You can currently use this command only on QFX5220-32CD switches.

Options

package-name Path and filename of the software package to be installed.

Additional Information

Starting in Junos OS Evolved Release 23.4R1, the `request system software validate-restart` command output summarizes the method required to perform the indicated upgrade. For example:

- Image validation succeeded. Application restart or Reboot is needed for this software image upgrade.
- Image validation succeeded. In-service kernel warm restart or Reboot is needed for this software image upgrade.
- Image validation succeeded. Reboot is needed for this software image upgrade.

Syntax

```
request system storage cleanup
<dry-run>
<no-confirm>
<re0  | re1 | routing-engine (backup | both | local | master | other)>
```

Syntax (EX Series Switches)

```
request system storage cleanup
<all-members>
<dry-run>
<local>
<member member-id>
<no-confirm>
```

```
<re0  | re1 | routing-engine (backup | both | local | master | other)>
<satellite [slot-id slot-id |device-alias  alias-name]>
```

Syntax (MX Series Router)

```
request system storage cleanup
<all-members>
<dry-run>
<local>
<member member-id>
<no-confirm>
<re0  | re1 | routing-engine (backup | both | local | master | other)>
<satellite [slot-id slot-id |device-alias  alias-name]>
```

Syntax (QFX Series)

```
request system storage cleanup
<component (serial number | UUID | all)>
<director-group name>
<dry-run>
<infrastructure name>
<interconnect-device name>
<name-tag name-tag>
<no-confirm>
<node-group name>
<prune>
<qfabric (component name) | dry-run | name-tag | repository)>
<repository (core | log)>
<re0  | re1 | routing-engine (backup | both | local | master | other)>
```

Syntax (SRX Series)

```
request system storage cleanup
<dry-run>
<no-confirm>
<re0  | re1 | routing-engine (backup | both | local | master | other)>
```

Description

Use this command to free storage space on the router or switch by rotating log files and proposing a list of files for deletion. On a QFabric system, you can delete debug files located on individual devices or on the entire QFabric system.

Options

all-members	(EX4200 switches and MX Series routers only) (Optional) Delete files on the Virtual Chassis primary Routing Engine only. To delete files on the other members of the Virtual Chassis configuration, log in to each backup Routing Engine and delete the files using the `request system storage cleanup local` command.
component (*UUID* | *serial number* | all)	(QFabric systems only) (Optional) Delete files located on individual QFabric system devices or on the entire QFabric system.
director-group *name*	(QFabric systems only) (Optional) Delete files on the director group.
dry-run	(Optional) List files proposed for deletion (without deleting them).
infrastructure *name*	(QFabric systems only) (Optional) Delete files on the fabric control Routing Engine and fabric manager Routing Engine.
interconnect-device *name*	(QFabric systems only) (Optional) Delete files on the Interconnect device.
local	(EX4200 switches and MX Series routers only) (Optional) Delete files on the local Virtual Chassis member.
member *member-id*	(EX4200 switches and MX Series routers only) (Optional) Delete files on the specified member of the Virtual Chassis configuration. For EX4200 switches, replace *member-id* with a value from 0 through 9. For an MX Series Virtual Chassis, replace *member-id* with a value of 0 or 1.
name-tag *name-tag*	(QFabric systems only) (Optional) Delete debug files that match a specific regular expression.
node-group *name*	(QFabric systems only) (Optional) Delete files on the Node group.
no-confirm	(Optional) Do not ask for confirmation before doing the cleanup.
prune	(QFabric systems only) (Optional) Delete debug files located in either the core or log debug repositories of a QFabric system device.

qfabric component *name*

(QFabric systems only) (Optional) Delete debug files located in the debug repositories of a QFabric system device.

(re0 | re1 | routing-engine (backup | both | local | master | other))

(Optional) Request operation on system storage on RE0, RE1, or on specified Routing Engine by these classifications: backup, both, local, primary, or other.

When Routing Engine is specified, the below message is shown before listing the files and deleting them.

```
Please check the list of files to be deleted using the dry-run option.
i.e.
request system storage cleanup dry-run
Do you want to proceed ? [yes,no] (no)
```

repository (core | log)

(QFabric systems only) (Optional) Specify the repository on the QFabric system device for which you want to delete debug files.

satellite [slot-id *slot-id* | device-alias *alias-name*]

(Junos Fusion only) (Optional) Specify the satellite device in the Junos Fusion by FPC ID or device alias name for which you want to delete debug files.

Additional Information

If logging is configured and being used, the `dry-run` option rotates the log files. In that case, the output displays the message “Currently rotating log files, please wait.” If no logging is currently under way, the output displays only a list of files to delete.

Required Privilege Level

maintenance

Output Fields

Table 130 on page 15378 describes the output fields for the `request system storage cleanup` command. Output fields are listed in the approximate order in which they appear.

Table 130: request system storage cleanup Output Fields

Field Name	Field Description
`List of files to delete:`	Shows list of files available for deletion.
`Size`	Size of the core-dump file.
`Date`	Last core-dump file modification date and time.
`Name`	Name of the core-dump file.
`Directory to delete:`	Shows list of directories available for deletion.
`Repository scope:`	Repository where core-dump files and log files are stored. The core-dump files are located in the `core` repository, and the log files are located in the `log` repository. The default `Repository scope` is shared since both the `core` and `log` repositories are shared by all of the QFabric system devices.
`Repository head:`	Name of the top-level repository location.
`Repository name:`	Name of the repository: `core` or `log`.
`Creating list of debug artifacts to be removed under:`	Shows location of files available for deletion.
`List of debug artifacts to be removed under:`	Shows list of files available for deletion.

Sample Output

request system storage cleanup dry-run

```
user@host> request system storage cleanup dry-run
Currently rotating log files, please wait.
```

```
This operation can take up to a minute.

Release Information

Command introduced in Junos OS Release 7.4.

`dry-run` option introduced in Junos OS Release 7.6.

`satellite` option introduced in Junos OS Release 14.2R3.

`no-confirm` and `(re0 |re1 | routing-engine (backup | both | local | master | other))` options introduced in Junos OS 17.3R1.

request system storage cleanup (Junos OS Evolved)

IN THIS SECTION

- Syntax | 15388
- Description | 15389
- Options | 15389
- Additional Information | 15390
- Required Privilege Level | 15390
- Sample Output | 15390
- Release Information | 15399

Syntax

```
request system storage cleanup (dry-run | force-deep | no-confirm)
```

Description

Use this command to free storage space on the router or switch by rotating log files and proposing a list of files for deletion.

The Junos OS Evolved implementation of the `request system storage cleanup` command is slightly different from the implementation on Junos OS:

- The system prompts you to specify the `dry-run` option:

```
Please check the list of files to be deleted using the dry-run option.
Continue anyway without checking? [yes,no] (yes)
```

- When you issue the `request system storage cleanup` command, Junos OS Evolved displays the types of files to be deleted. See the Sample Output section below for an example.
- Prior to Junos OS Evolved Release 20.1R1, the command cleans up any ISO files on the system, rotates system log files, and clears trace files. It does not remove user-created files. Starting in Junos OS Evolved Release 20.1R1, this command does not remove ISO images from the system. It removes all core files, log files from **/var/log/**, and all **/var/log/*** files. To remove old images from the device, use the `request system software delete` command.
- In Junos OS Evolved, the system computes the available space and emits o/p on console for reference.

In Junos OS Evolved, the `request system storage cleanup | display xml rpc` command displays different XML tags for different file types. In Junos OS, the command displays only the `file` tag for all types of files. For more information about the differences between Junos OS and Junos OS Evolved, see How Junos OS Evolved Differs from Junos OS.

Options

dry-run (Prompted if not specified) List the files proposed for deletion (without deleting the files).

force-deep (Optional) Deep clean all temporary files and rotate logs. This option cleans up all the user-created files under the **/tmp** and **/var/tmp** directories.

no-confirm (Optional) Do not ask for confirmation before doing the cleanup.

Additional Information

If logging is configured and being used, the `dry-run` option rotates the log files. In that case, the output displays the message “Currently rotating log files, please wait”. If no logging is currently under way, the output displays only a list of files to delete.

Required Privilege Level

maintenance

Sample Output

request system storage cleanup (Junos OS Evolved)

```
user@host-re0> request system storage cleanup
Please check the list of files to be deleted using the dry-run option.
Continue anyway without checking? [yes,no] (no) yes

Release Information

Command introduced in Junos OS Evolved Release 20.4R2.

RELATED DOCUMENTATION

request system software delete (Junos OS Evolved) | **15254**

request system storage cleanup (SRX Series)

IN THIS SECTION

- Syntax | 15400
- Description | 15400
- Options | 15400
- Additional Information | 15400
- Required Privilege Level | 15401
- Output Fields | 15401
- Sample Output | 15401
- Release Information | 15404

Syntax

```
request system storage cleanup <dry-run>
```

Description

Use this command to free storage space on the device by rotating log files and proposing a list of files for deletion.

Options

dry-run (Optional) List files proposed for deletion (without deleting them).

Additional Information

If logging is configured and being used, the `dry-run` option rotates the log files. In that case, the output displays the message “Currently rotating log files, please wait.” If no logging is currently under way, the output displays only a list of files to delete.

Required Privilege Level

maintenance

Output Fields

Table 131 on page 15401 describes the output fields for the `request system storage cleanup` command. Output fields are listed in the approximate order in which they appear.

Table 131: request system storage cleanup Output Fields

Field Name	Field Description
`List of files to delete:`	Shows list of files available for deletion.
`Size`	Size of the core-dump file.
`Date`	Last core-dump file modification date and time.
`Name`	Name of the core-dump file.

Sample Output

request system storage cleanup dry-run

```
user@host> request system storage cleanup dry-run
List of files to delete:

request system yang add

IN THIS SECTION

- Syntax | 15405
- Description | 15405
- Options | 15406
- Required Privilege Level | 15406
- Sample Output | 15407
- Release Information | 15407

Syntax

```
request system yang add package package-name module [modules]
<action-script [scripts]>
<translation-script [scripts]>
<deviation-module [modules]>
<proxy-xml>
<snmp>
```

Description

Define a new YANG package with the modules, deviation modules, and scripts that are added to the device as part of the package, and merge the data models defined in the modules with the Junos OS schema. When you add a custom YANG data model to the device, you must also add at least one translation script or one action script, which provides the mapping between the new data model and Junos OS. To add multiple modules or scripts, include a space-delimited list of absolute or relative file paths enclosed in brackets.

> **NOTE**: To install OpenConfig modules that are packaged as a compressed tar file, use the `request system software add` command. OpenConfig modules and scripts that are installed using the `request system software add` command are always associated with the package identifier `openconfig`.

When you create a new package, the device stores copies of the module and script files in a new location. The device also stores copies of the action script and translation script files under the **/var/db/scripts/action** and **/var/db/scripts/translation** directories, respectively. Junos OS validates the syntax of the modules and scripts, rebuilds its schema to include the new data models, and then validates the active configuration against this schema. Newly added RPCs and configuration hierarchies are immediately available for use.

> **NOTE**: Devices that use the ephemeral configuration database will delete all ephemeral configuration data in the process of rebuilding the schema.

> **NOTE**: To prevent CLI-related or configuration database errors, we recommend that you do not perform any CLI operations, change the configuration, or terminate the operation while a device is in the process of adding, updating, or deleting a YANG package and modifying the schema.

> **NOTE**: Starting in Junos OS Release 18.3R1, adding, deleting, or updating YANG packages in configuration mode with the `run` command is not supported.

Options

action-script [*scripts*]	List of paths for one or more action scripts to add to the device as part of the package.
module [*modules*]	List of paths for one or more YANG modules to add to the device as part of the package. The device merges the data models defined in the modules with the Junos OS schema.
deviation-module [*modules*]	(Optional) List of paths for one or more modules that define deviation statements that should be applied to modules in the package.
package *package-name*	User-defined identifier that represents the collection of YANG modules and scripts.
proxy-xml	(Optional) Specify that `module` is a list of paths for one or more modules that provide user-defined OpenConfig mappings for the XML Proxy process to translate Junos Telemetry Interface statistics exported through gRPC into key-value pairs.
snmp	(Optional) Specify that `module` is a list of paths for one or more YANG modules that define custom MIBs. The system converts the modules to JSON format, and the snmpd process parses the JSON data and builds its internal database.
translation-script [*scripts*]	List of paths for one or more translation scripts to add to the device as part of a package. YANG modules that define configuration data models require one or more translation scripts to map the nonnative configuration syntax to the corresponding Junos OS syntax.

Required Privilege Level

maintenance

Sample Output

request system yang add

```
user@host> request system yang add package p1 module [yang/if.yang yang/if-aggregate.yang
yang/if-show.yang] deviation-module yang/deviation/if-devs.yang translation-script translation/
if.slax action-script action/if-show.py

request system yang delete

IN THIS SECTION

- Syntax | **15408**
- Description | **15408**
- Options | **15409**
- Required Privilege Level | **15409**
- Sample Output | **15410**
- Release Information | **15410**

Syntax

```
request system yang delete package-name
```

Description

Remove the given YANG package and all of its modules and scripts from the device, and remove the data models associated with that package from the Junos OS schema.

CAUTION: Before you delete a YANG package, ensure that the active configuration does not contain configuration data that has dependencies on the data models added by that package.

> **NOTE**: You must use the `request system software delete` command to remove OpenConfig packages that were installed from a compressed tar file using the `request system software add` command.

When you delete a package, Junos OS rebuilds its schema to remove the data models associated with that package and then validates the active configuration against the newly updated schema. The device removes the copies of the module and script files that were generated when the package was created. The device also removes the copies of the package's action script and translation script files that are stored under the **/var/db/scripts/action** and **/var/db/scripts/translation** directories. If you downloaded the original module and script files to a different location, the original files remain unchanged.

> **NOTE**: Devices that use the ephemeral configuration database will delete all ephemeral configuration data in the process of rebuilding the schema.

> **NOTE**: To prevent CLI-related or configuration database errors, we recommend that you do not perform any CLI operations, change the configuration, or terminate the operation while a device is in the process of adding, updating, or deleting a YANG package and modifying the schema.

> **NOTE**: Starting in Junos OS Release 18.3R1, adding, deleting, or updating YANG packages in configuration mode with the `run` command is not supported.

Options

package-name	Name of the YANG package to remove.

- Description | **15411**

- Options | 15412
- Required Privilege Level | 15412
- Sample Output | 15412
- Release Information | 15412

Syntax

```
request system yang disable package-name
```

Description

Disable the translation scripts associated with the given YANG package.

Translation scripts convert configuration data corresponding to YANG data models into Junos OS syntax and add the translated configuration data as a transient change in the checkout configuration during the commit operation. Translation scripts are enabled by default as soon as you add the scripts and related YANG modules to the device using the appropriate operational command.

Use this command to temporarily disable translation scripts for a package to help troubleshoot translation issues instead of deleting the entire package, which would remove the associated data models from the Junos OS schema as well as remove the package and related files from the device. After you disable translation for a package and commit the configuration, the configuration data associated with the YANG data models in that package can be present in the active configuration, but the configuration has no impact on the functioning of the device.

When translation is disabled, you can still configure and commit the statements and hierarchies in the data models added by that package. However, the device does not commit the corresponding Junos OS configuration statements as transient changes during the commit operation for any statements in the data models added by that package, even for those statements that were committed prior to disabling translation.

NOTE: When you disable translation for a package, the device retains any transient configuration changes that were committed prior to disabling translation until the next commit operation.

> **TIP**: Use the `show system yang package` *`package-name`* command to verify the translation status of a package.

Options

package-name Name of the YANG package for which to disable translation.

Required Privilege Level

maintenance

Sample Output

request system yang disable

```
user@host> request system yang disable p1
user@host>
```

Syntax

```
request system yang update package-name action-script [scripts] deviation-module [modules]
module [modules] proxy-xml [file-path-names] translation-script [scripts]
```

Description

Update an existing YANG package to include new or modified YANG modules or scripts, and merge the updated data models in that package with the Junos OS schema.

When you update a package, the device stores copies of the new and modified module and script files. Junos OS then rebuilds its schema to include the changes to the data models and validates the active configuration against this schema.

NOTE: Devices that use the ephemeral configuration database will delete all ephemeral configuration data in the process of rebuilding the schema.

NOTE: To prevent CLI-related or configuration database errors, we recommend that you do not perform any CLI operations, change the configuration, or terminate the operation while a device is in the process of adding, updating, or deleting a YANG package and modifying the schema.

NOTE: Starting in Junos OS Release 18.3R1, adding, deleting, or updating YANG packages in configuration mode with the `run` command is not supported.

Options

package-name	Name of the YANG package to update.
action-script [*scripts*]	List of paths for one or more action scripts to add to or update in the package.

deviation-module [*modules*]	List of paths for one or more deviation modules to add to or update in the package.

Configure a NETCONF Proxy Telemetry Sensor in Junos

request system zeroize

IN THIS SECTION

- Syntax | 15419
- Description | 15419
- Options | 15419
- Required Privilege Level | 15420
- Sample Output | 15420

Syntax

```
request system zeroize <media>
```

Description

Use this command to remove all configuration information and resets all key values. The command removes all data files, including customized configuration and log files, by unlinking the files from their directories. If the device has two Routing Engines, the command is broadcast to both Routing Engines on the device. As a result, both Routing Engines are zeroized.

The command removes all user-created files from the system including all plain-text passwords, secrets, and private keys for SSH, local encryption, local authentication, IPsec, RADIUS, TACACS+, and SNMP.

This command reboots the device and sets it to the factory default configuration. After the reboot, you cannot access the device through the management Ethernet interface. Log in through the console as root and start the Junos OS CLI by typing `cli` at the prompt.

Options

media (Optional) In addition to removing all configuration and log files, the media option causes memory and the media to be scrubbed, removing all traces of any user-created files. Every storage device attached to the system is scrubbed, including disks, flash drives, removable USBs, and the like. The duration of the scrubbing process is dependent on the size of the media being erased. As a result, the request system zeroize media operation can take considerably more time

than the request system zeroize operation. However, the critical security parameters are all removed at the beginning of the process.

> **NOTE**: The `media` option is not supported on SRX5000 line devices.

Required Privilege Level

Not applicable.

Sample Output

request system zeroize

```
user@host> request system zeroize
warning: System will be rebooted and may not boot without configuration

Erase all data, including configuration and log files?. In case of Dual RE system, both Routing
Engines will be zeroized [yes,no] (no) yes

RELATED DOCUMENTATION

request system software rollback (SRX Series)

request system zeroize (Junos OS)

IN THIS SECTION

- Syntax | 15421
- Description | 15421
- Options | 15423
- Required Privilege Level | 15423
- Sample Output | 15423
- Release Information | 15425

Syntax

```
request system zeroize
<media>
<local>
```

Description

Use this command to remove all configuration information on the Routing Engines and reset all key values on the device where you run the command.

- If the device has dual Routing Engines, the command is broadcast to all Routing Engines on the device. As a result, both Routing Engines are zeroized.
- In a Virtual Chassis or Virtual Chassis Fabric (VCF) composed of EX Series switches (except EX8200 Virtual Chassis) or QFX Series switches, this command operates only on the member switch where you run the command, even if that switch is in the primary Routing Engine role. The command is not forwarded to the backup Routing Engine member or to member switches in the line-card role. To apply this command to more than one member of an EX Series or QFX Series Virtual Chassis or VCF, we recommend you remove and disconnect each of those members from the Virtual Chassis or VCF, and then run the command on each isolated switch individually.

This command removes all data files, including customized configuration and log files, by unlinking the files from their directories. The command removes all user-created files from the system, including all plain-text passwords, secrets, and private keys for SSH, local encryption, local authentication, IPsec, RADIUS, TACACS+, and SNMP.

This command reboots the device and sets it to the factory default configuration. After the reboot, you cannot access the device through the management Ethernet interface. Log in through the console as `root` and start the Junos OS CLI by typing `cli` at the prompt.

If the configuration contains the `commit synchronize` statement at the `[edit system]` hierarchy level, and you issue a `commit` in the primary Routing Engine, the primary configuration is automatically synchronized with the backup. If the backup Routing Engine is down when you issue the `commit`, the Junos OS displays a warning and commits the candidate configuration in the primary Routing Engine. When the backup Routing Engine comes up, its configuration will automatically be synchronized with the primary. A newly inserted backup Routing Engine or a Routing Engine that comes up after running the `request system zeroize` command also automatically synchronizes its configuration with the primary Routing Engine configuration.

Starting with Junos OS Release 15.1F3, the `request system zeroize` command removes all configuration information on the guest OS for the PTX5000 router with RE-DUO-C2600-16G, and MX240, MX480, and MX960 with RE-S-1800X4-32G-S.

Starting with Junos OS Release 15.1F5, the `request system zeroize` command removes all configuration information on the guest OS for the MX2010 and MX2020 with REMX2K-1800-32G-S.

On these routers, in order to remove all configuration information on both guest OS and host OS, use the `request vmhost zeroize` command.

To completely erase user-created data so that it is unrecoverable, use the `media` option.

Options

media (Optional) In addition to removing all configuration and log files, causes memory and the media to be scrubbed, removing all traces of any user-created files. Every storage device attached to the system is scrubbed, including disks, flash drives, removable USBs, and so on. The duration of the scrubbing process is dependent on the size of the media being erased. As a result, the `request system zeroize media` operation can take considerably more time than the `request system zeroize` operation. However, the critical security parameters are all removed at the beginning of the process.

On QFX Series platforms running Junos OS Release 14.1X53 or earlier, the `media` option is not available. On QFX Series platforms running releases later than Junos OS Release 14.1X53 that do not have the upgraded FreeBSD kernel (10+), the `media` option is available, but if you use it, the system will issue a warning that the `media` option is not supported and will continue with the zeroize operation. On platforms that are not QFX Series platforms, the `media` option is not available in Junos OS Release 17.2 or later with Junos with upgraded FreeBSD.

local (Optional) Remove all the configuration information and restore all the key values on the active Routing Engine.

> **CAUTION**: The `local` option is not available on devices that run Junos OS Evolved, so if you execute `request system zeroize` on those devices and they have dual Routing Engines, all Routing Engines on the local chassis are rebooted. See the Junos® OS Evolved Software Installation and Upgrade Guide.

Specifying this option has no effect on switches in a Virtual Chassis or VCF composed of EX Series switches (except EX8200 Virtual Chassis) or QFX switches, because in these configurations, the `request system zeroize` command only operates locally by default.

Required Privilege Level

maintenance

- Determine whether both Routing Engines are Booted from the Same Disk | **15428**
- Required Privilege Level | **15428**

Sample Output | 15428
Release Information | 15430

Syntax

```
request system zeroize <(disk1 | disk2)>
```

Description

Use this command to sanitize the disks on a Routing Engine, to make it difficult to access data on the disks, using various levels of sanitization corresponding to degrees of difficulty, as defined in the NIST 800-88 standard. If the device has two Routing Engines, the command is broadcast to both Routing Engines on the device. As a result, both Routing Engines are zeroized. When you issue this command, the console logs show which sanitization level was actually used on the disks. The console logs also provide a list of the erase procedures supported by the disk. The same list order is used by this command to erase the disk. If any erase procedure fails, the next erase mechanism is tried, and so on, until the last erase mechanism is what is used to sanitize the disk.

Starting in Junos OS Evolved Release 21.3R1, for devices that support this feature, if the disks in the Routing Engine support the ATA standard, this command sanitizes the disks on the Routing Engine using the ATA `secure erase` command to overwrite the data. The ATA `secure erase` command overwrites the contents of LBA 0 through the greater of either READ NATIVE MAX or READ NATIVE MAX EXT, and replaces the contents with 0s or 1s. If the disks do not support the ATA standard (for example, they support the SCSI standard), they are sanitized using the older method described below. The secure erase capability is classified under the CLEAR NIST media sanitization level, according to the NIST 800-88 standard. When the secure erase is complete, the system copies the current running OS from RAMDISK to the ATA disk. Once the current running OS is installed, the system reboots and comes back to the factory default configuration.

Starting in Junos OS Evolved 24.4R1, for devices that support this feature, if the disks in the Routing Engine support the SATA standard, this command sanitizes the disks using the PURGE NIST media sanitization level, according to the NIST 800-88 standard. The PURGE level is comprised of both the CRYPTO_SCRAMBLE (if supported by the SATA SSD controller) and the BLOCK_ERASE mechanisms. The CRYPTO_ERASE mechanism (if supported by the SATA SSD controller) is followed by the BLOCK_ERASE mechanism in all cases of sanitization. Whenever the CRYPTO_SCRAMBLE mechanism is not supported, only the BLOCK_ERASE mechanism is run. When the disk sanitization is complete, the system copies the current running OS from RAMDISK to the SATA disk. Once the current running OS is installed, the system reboots and comes back to the factory default configuration.

Prior to Junos OS Evolved Release 21.3R1, and in any release for disks that do not support the NIST 800-88 sanitization standard, this command removes all data files, including any customized configuration and log files, by unlinking the files from their directories. The command removes all user-created files from the system, including all plain-text passwords, secrets, and private keys for SSH, local encryption, local authentication, IPSec, RADIUS, TACACS+, and SNMP.

This command reboots the device and sets it to the factory default configuration. After the reboot, you cannot access the device through the management Ethernet interface. Log in through the console as `root` and start the CLI by typing `cli` at the prompt.

Options

(disk1 | disk2) (For Routing Engines that contain two disks only. For Routing Engines that contain only one disk, the (disk1|disk2) option does not apply.) The `disk1` and `disk2` options refer to the absolute disk; that is, to the primary disk and to the snapshot disk, respectively. One use case for this option is when you need to replace a disk on the Routing Engine, and you want to securely erase the information before removing the disk from the Routing Engine.

The `request system zeroize disk1` command secure erases the primary disk and installs the current running Junos OS Evolved version on the Routing Engine (or on the primary disk on both Routing Engines in a chassis-based system. The contents on disk 2 (that is, the snapshot disk) remain **unchanged**.

The `request system zeroize disk2` command secure erases the snapshot disk and installs the current running Junos OS Evolved version on the Routing Engine (or on the secondary disk on both Routing Engines in a chassis-based system). The contents on disk 1 (that is, the primary disk) remain **unchanged**.

When you use any zeroize option that cleans the active disk (disk 1 in the case of primary boot or disk 2 in the case of snapshot boot), the system automatically reboots to finish the zeroize of the active disk. When you zeroize the backup disk (that is, disk 2 in the case of primary boot or disk 1 in the case of snapshot boot), the system does not reboot.

Note that the behavior of the `request system zeroize (disk1 | disk2)` command is non-deterministic in a dual Routing Engine system where one Routing Engine is in snapshot boot and other Routing Engine is in primary boot. For example, if the primary Routing Engine is in primary boot and the backup Routing Engine is in snapshot boot, then the `request system zeroize disk1` command acts on the active disk in the primary Routing Engine and on the backup disk in the backup Routing Engine. Because the primary Routing Engine reboots the chassis after zeroizing its active disk, the backup Routing Engine, which is zeroizing its snapshot disk, is interrupted by the reboot and the data on its snapshot disk will be inconsistent. Therefore, the final behavior is non-deterministic in the case of the master and backup Routing Engine, because they are running from different boot disks.

Default: Zeroize all disks and both Routing Engines, if applicable. The default order is to first create a snapshot on secondary disk and then to install the OS on the primary disk. There is no difference in behavior between single Routing Engine or dual Routing Engine systems, except that for dual Routing Engine systems, the command is run on both Routing Engines.

Determine whether both Routing Engines are Booted from the Same Disk

Log in into both Routing Engines. The `show system software list` command displays a banner if the Routing Engine was booted from the snapshot disk (disk2). The same command doesn't display a banner if the Routing Engine was booted from the primary disk (disk1). In this way, you can check if both Routing Engines are booted from the same disk. For example, if the command `show system software list` on RE0 does not display a banner for booting from snapshot and RE1 shows a banner, then RE0 was booted from its primary disk, but RE1 was booted from its snapshot disk instead.

In case of issues, you can boot the affected Routing Engine from either disk1 or disk2, whichever disk did not boot from the required disk. Both Routing Engines may boot from disk1 or disk2, based on where this command was issued.

Required Privilege Level

maintenance

Sample Output

request system zeroize

```
user@host> request system zeroize
warning: System will be rebooted and may not boot without configuration

Erase all data, including configuration and log files?. In case of Dual RE system, both Routing
Engines will be zeroized [yes,no] (yes)
```

Example: Console logs for SATA drive sanitization

```
user@host> request system zeroize

request system zeroize ztp-option secure

IN THIS SECTION

- Syntax | **15431**
- Description | **15431**
- Options | **15431**
- Required Privilege Level | **15431**
- Sample Output | **15431**

Release Information | 15432

Syntax

```
request system zeroize ztp-option secure-(enable | disable)
```

Description

On secure devices, you can switch between using secure zero-touch provisioning (SZTP) and zero-touch provisioning (ZTP).

Options

enable The CLI checks to see if the device is a secure device. If the device is secure, the process ends. The next time the device boots, the device uses secure ZTP as the provisioning solution. If the device is not a secure device, you will receive an error message that says the device is not secure, and the process ends.

disable The CLI checks to see if the device is a secure device. If the device is secure, the next time the device boots, the device uses ZTP as the provisioning solution. If the device is not secure, the process ends.

Required Privilege Level

maintenance

Sample Output

request system zeroize ztp-option secure-enable

```
user@device> request system zeroize ztp-option secure-enable
```

request system zeroize ztp-option secure-disable

```
user@device> request system zeroize ztp-option secure-disable
```

Release Information

Command introduced in Junos OS Evolved Release 23.2.

```
request unified-edge tdf call-trace start
<imsi imsi>
<msisdn msisdn>
<next-call next-call>
<routing-instance routing-instance>
<subscriber-name string>
<user-name string>
<v4-addr v4-addr>
<v6-addr v6-addr>
```

Description

Start TDF subscriber call tracing.

Options

none	Start call tracing for all TDF subscribers.
imsi *imsi*	(Optional) Start the call tracing for subscribers with the specified International Mobile Subscriber Identity (IMSI) number.
msisdn *msisdn*	(Optional) Start call tracing for subscribers with the specified Mobile station ISDN (MSIDSN) number.
next-call *next-call*	(Optional) Start call tracing for the specified number of next call events (1 through 50). For example, if you specify 10, then the next 10 calls are traced.

> **NOTE**: If you do not include the `next-call` keyword while tracing subscribers on a domain, the default value of 1 is used.

routing-instance *routing-instance* — (Optional) Start call tracing for subscribers for the specified routing instance.

subscriber-name *string* — (Optional) Start call tracing for the specified IFL-based subscriber.

user-name *string* — (Optional) Start call tracing for the specified IP-based subscriber.

v4-addr *v4-addr* — (Optional) Start call tracing for subscribers for the specified IPv4 address of the subscriber's user equipment (UE).

v6-addr *v6-addr* — (Optional) Start call tracing for subscribers for the specified IPv6 address of the subscriber's user equipment.

request virtual-chassis device-reachability

IN THIS SECTION

- Syntax | 15448
- Description | 15448
- Options | 15448
- Required Privilege Level | 15449
- Output Fields | 15449
- Sample Output | 15450
- Release Information | 15450

Syntax

```
request virtual-chassis device-reachability test-name name  (source-fpc source-fpc-id | source-
ip-address source-ip-address) (destination-device device-id | destination-fpc destination-fpc-id
| destination-ip-address destination-ip-address)
<probe-count count>
<probe-interval interval>
<probe-pattern pattern>
<test-count count>
<test-interval interval>
```

Description

Run a Virtual Chassis device reachability test. A Virtual Chassis device reachability test sends ping packets from one member of a Virtual Chassis to another member of a Virtual Chassis directly through the Virtual Chassis connections. The receiving Virtual Chassis member sends reply packets to confirm receipt of the ping packets from the sending device. The results of the test immediately provide information that is helpful in verifying connectivity between Virtual Chassis member devices.

Options

test-name *name*	Specify the name of the test. The name can be any single-word character string. Spaces are not allowed.
source-fpc *source-fpc-id*	Specify the FPC that sends the first ping message.
source-ip-address *source-ip-address*	Specify the source IP address that receives the ping message.
destination-device *device-id*	Specify the device in the Virtual Chassis that receives the ping message.
destination-fpc *destination-fpc-id*	Specify the FPC that receives the first ping message.
destination-ip-address *destination-ip-address*	Specify the destination IP address that receives the ping message.
probe-count *count*	(Optional) Specify the number of ping messages to send for the test. The count can be any number from 1 through 10. The default count is 5.
probe-interval *interval*	(Optional) Specify the time in seconds between the ping messages that are sent during the test. The interval can be any number from 1 through 3. The default interval is 1 second.

probe-pattern *pattern* (Optional) Specify a payload pattern in the ping message. Enter the pattern in hexadecimal format.

test-count *count* (Optional) Specify the number of times to run the test. The count can be any number from 1 through 3. The default count is 1.

test-interval *interval* (Optional) Specify the time in seconds between tests when multiple tests are specified. The interval can be any number from 1 through 3. The default interval is 1.

Required Privilege Level

system-control

Output Fields

Table 135 on page 15449 lists the output fields for the `request virtual chassis device reachability` command. Output fields are listed in the approximate order in which they appear.

Table 135: request virtual chassis device reachability Output Fields

Field Name	Field Description
Test Name	The name of the test.
Performing Test	The test number.
Session ID	The session ID. This output is always **0** and not useful for Virtual Chassis device reachability tests.
Packets Count/Sent/Received/Sendfail	The number of total ping packets sent, including the total number of ping packets counted (**Count**), sent (**Sent**), received (**Received**), and packets that could not be sent (**Sendfail**).
Unknown/Timedout/Duplicate packets received	The failed pings, including the number of ping packets that failed for an unknown reason (**Unknown**), timed out (**Timed Out**), and the number of duplicate received ping packets (**Duplicate packets received**).

Table 135: request virtual chassis device reachability Output Fields *(Continued)*

Field Name	Field Description
Round-trip Min/Avg/Max	The average round-trip ping time, including the shortest ping time (**Min**), the average ping time (**Avg**), and the maximum ping time (**Max**).

Sample Output

request virtual-chassis device-reachability test-name member0-to-member2 source-fpc 0 destination-fpc 2

```

Verifying Connectivity Between Virtual Chassis Member Devices

request virtual-chassis member-id delete (MX Series Virtual Chassis)

IN THIS SECTION

- Syntax | 15451
- Description | 15451
- Required Privilege Level | 15451
- Sample Output | 15452
- Release Information | 15452

Syntax

```
request virtual-chassis member-id delete
<force>
```

Description

Remove (**delete**) the member ID from a router or switch that you want to remove from a Virtual Chassis configuration.

> **NOTE**: Issuing the command to remove the member ID causes the device to reboot, and requires you to confirm that you want to proceed with this operation. If you do not confirm the operation, the software cancels the command. You can alternatively use the `force` option to reboot without requiring confirmation.

Required Privilege Level

system-control

Sample Output

request virtual-chassis member-id delete

```
user@host> request virtual-chassis member-id delete
This command will disable virtual-chassis mode and reboot the system.
 Continue? [yes,no] (no)
```

Release Information

Command introduced in Junos OS Release 11.2.

request virtual-chassis member-id set

IN THIS SECTION

- Syntax | 15453
- Syntax (MX960, MX2010, and MX2020 Routers) | 15453
- Description | 15453
- Options | 15453
- Required Privilege Level | 15454
- Sample Output | 15454
- Release Information | 15454

Syntax

```
request virtual-chassis member-id set member member-id
```

Syntax (MX960, MX2010, and MX2020 Routers)

```
request virtual-chassis member-id set member member-id
<slots-per-chassis slot-count>
```

Description

Assign (`set`) a member ID and, optionally, a slot count to a router or switch that you want to add as a member of a Virtual Chassis configuration.

> **NOTE**: Issuing the `request virtual-chassis member-id set` command causes the device to reboot, and requires you to confirm that you want to proceed with this operation. If you do not confirm the operation, the software cancels the command. After the reboot all MPCs remain powered off until the Virtual Chassis port connection is configured.

Options

member *member-id*

Assign the numeric value that identifies a member router or switch in a Virtual Chassis configuration. When you assign a member ID to a router or switch, assign the same member ID defined for this device in the preprovisioned configuration. Replace *member-id* with the value 0 or 1.

slots-per-chassis *slot-count*

(MX960, MX2010, and MX2020 routers) (Optional) Identify the number of chassis slots in the Virtual Chassis member router. To ensure that a Virtual Chassis consisting of an MX2020 member router and either an MX960 or MX2010 member router forms properly, you must explicitly set the *slot-count* value for the MX960 router or MX2010 router to 20 to match the slot count of the MX2020 router.

- Values:

  The valid values for *slot-count* are as follows:

- MX960 router: 12 or 20
- MX2010 router: 12 or 20
- MX2020 router: 20

- Default:

  The default values for *slot-count* are as follows:

  - MX960 router: 12
  - MX2010 router: 12
  - MX2020 router: 20

Required Privilege Level

system-control

Sample Output

request virtual-chassis member-id set (Assigning a Member ID)

```
user@host> request virtual-chassis member-id set member 0
This command will enable virtual-chassis mode and reboot the system.
 Continue? [yes,no] (no)
```

request virtual-chassis member-id set (Assigning a Member ID and Slot Count)

```
user@host> request virtual-chassis member-id set member 1 slots-per-chassis 20
This command will enable virtual-chassis mode and reboot the system.
 Continue? [yes,no] (no)
```

Release Information

Command introduced in Junos OS Release 11.2.

`slots-per-chassis` option added in Junos OS Release 15.1 for MX960 routers, MX2010 routers, and MX2020 routers.

Syntax

```
request virtual-chassis mode
    fabric
    mixed <ieee-clause-82>
    hgoe
    network-port
    <disable>
    <reboot>
    <all-members> | <local> | <member member-id>
```

Description

Enable special device modes when operating as part of a Virtual Chassis or Virtual Chassis Fabric (VCF). Supported device modes include:

- Fabric mode—Enable the device to operate as part of a VCF. You must set `fabric` mode on all of the devices in a VCF.
- Mixed mode—Enable the device to operate in a mixed Virtual Chassis or VCF.
- (EX4100 and EX4400 switches only) Network port mode—Enable the default Virtual Chassis ports (VCPs) to operate as network ports instead of as VCPs.

You must reboot the standalone device, Virtual Chassis or VCF for this command to take effect, and the setting persists across subsequent reboot operations. You can use this command's `reboot` option to automatically reboot the device when setting or disabling a device mode.

> **NOTE**: For devices in a mixed VCF, you can set both mixed and fabric modes in the same command and then reboot the device once for both settings to take effect.

Mixed Mode Requirements and Best Practices

You must set `mixed` mode on all devices in a Virtual Chassis or a VCF when the devices have differences in how they interoperate. See Understanding Mixed EX Series and QFX Series Virtual Chassis or *Understanding Mixed Virtual Chassis Fabric* for details on which devices can be combined to form a mixed Virtual Chassis or VCF.

Some combinations of different types of switches form non-mixed Virtual Chassis or VCFs because the devices can run the same software images. You *don't* need to configure mixed mode if the only devices in your Virtual Chassis are the following combinations of switches:

- Only EX4500 and EX4550 switches in an EX Series Virtual Chassis.
- EX2300 multigigabit switches (EX2300-24MP and EX2300-48MP models) with any other EX2300 model switches in an EX2300 Virtual Chassis.
- EX4100 multigigabit switches (EX4100-24MP and EX4100-48MP models) with any other EX4100 model switches in an EX4100 Virtual Chassis.
- EX4400 multigigabit switches (EX4400-24MP and EX4400-48MP models) with any other EX4400 model switches in an EX4400 Virtual Chassis.
- Only QFX3500 and QFX3600 switches in a QFX Series Virtual Chassis.
- QFX5110 and QFX5100 switches in a QFX5110 Virtual Chassis or QFX5110 VCF.

However, EX4300 switches that are not multigigabit models combined with EX4300 multigigabit model (EX4300-48MP) switches form a mixed EX4300 Virtual Chassis. In this case, you must set mixed mode on all member switches. In addition, when you set mixed mode on the EX4300 non-multigigabit model member switches, you must include the `ieee-clause-82` option with the mode command. This option sets a special port mode (IEEE Clause 82) on the Virtual Chassis ports (VCPs) that enables them to communicate when interconnected with VCPs on EX4300 multigigabit switches.

> **NOTE**: If you remove an EX4300 member switch from a mixed EX4300 Virtual Chassis with multigigabit model members, you must disable `ieee-clause-82` port mode on the switch if you want to reconfigure it as a standalone switch or use it in any other type of mixed Virtual Chassis or any non-mixed Virtual Chassis. Otherwise, the VCPs will not connect with other members in the new Virtual Chassis. To do this, use the `request virtual-chassis mode mixed ieee-clause-82 disable` command and then reboot the switch. To add the switch to any other type of mixed Virtual Chassis, enable mixed mode again without this option and reboot the switch again for the change to take effect.

Best practices when setting `mixed` mode include:

- Don't enable mixed mode on a standalone device or for a member switch that is in a non-mixed Virtual Chassis or VCF. Mixed mode reduces the maximum scaling numbers for some features on the standalone switch, Virtual Chassis, or VCF to accommodate different types of devices that can be interconnected.

- To avoid potential traffic disruptions and configuration issues, on each device we recommend setting mixed mode for a mixed Virtual Chassis or VCF before cabling them into a mixed Virtual Chassis or VCF. You must then reboot the device, Virtual Chassis or VCF for the mode change to take effect.

  > **NOTE**: The same best practice applies to setting fabric mode for a VCF—set this mode on the member devices before interconnecting them.

- You can change mode settings manually after a device has been added to a Virtual Chassis or VCF if you determine the settings are not the same on all the devices.

  However, if you set only some of the devices in a mixed Virtual Chassis or VCF to mixed mode, the mixed Virtual Chassis or VCF might not form. If you experience this issue, enter the `request virtual-chassis mode mixed all-members` command to force setting mixed mode on all devices in the Virtual Chassis or VCF. (Include the `fabric` mode option as well for a VCF.) You can then reboot the entire Virtual Chassis or VCF, or only the devices where the mode changed. The Virtual Chassis or VCF forms when the rebooted devices are online again.

> **NOTE**: On switches running Junos OS Release 11.4 or later, if you don't set any of the switches in a mixed EX4200 and EX4500 Virtual Chassis to mixed mode, a mixed EX4200 and EX4500 Virtual Chassis forms where one of the switches assumes the primary role, and all other switches take on the linecard role. If you see this behavior, enter the `request virtual-chassis mode mixed all-members` command to set all members to mixed mode and reboot the Virtual Chassis.

Network Port Mode (EX4100 and EX4400 Switches Only)

If you are not using an EX4100 or EX4400 switch as a member switch in a Virtual Chassis, you can use this command with the `network-port` option to enable network port mode, which converts the default VCPs on the switch into network ports. By default, the two 100-Gigabit Ethernet QSFP28 ports on the rear panel are set as two logical 50-Gbps VCP interfaces each, forming a total of four logical 50-Gbps VCPs. (The default VCPs are in PIC slot 1, so the VCP interfaces are named vcp-255/1/0 through vcp-255/1/3.) If you convert these ports into network port mode, they become two 100 Gigabit Ethernet network ports, or you can channelize each of them into four 25-Gigabit Ethernet or four 10-Gigabit Ethernet network ports.

You can't use one of the rear panel 100-Gigabit Ethernet ports as a VCP and the other as a network port. When you use this command to enable network port mode, the mode affects both 100-Gbps ports together.

You can use the `show virtual-chassis mode` command to see the current port mode and what the port mode will be the next time the switch is rebooted. The two values might be different if you changed the mode but have not rebooted the switch yet.

To disable network port mode and return these ports to their default settings as VCPs, use the `network-port` and `disable` options with the `request virtual-chassis mode` command. You must reboot the switch for network port mode changes to take effect, so you can include the reboot option in the same command. For example:

```
request virtual-chassis mode network-port disable reboot
```

You can use the `request virtual-chassis vc-port delete` command to disable one of these ports as a VCP, but that action doesn't change the port mode to network port mode. You must enter the `request virtual-chassis mode network-port` command (and reboot the switch) to use the port as a network port. Also, if you run the `request virtual-chassis vc-port delete interface` *`interface-name`* command to disable vcp-255/1/0, that command disables both logical ports 0 and 1 (vcp-255/1/0 and vcp-255/1/1). Similarly, specifying to disable vcp-255/1/2 disables both logical ports 2 and 3 (vcp-255/1/2 and vcp-255/1/3).

Options

all-members (Optional) Set the Virtual Chassis mode for all members of the Virtual Chassis or VCF.

disable Disable the specified Virtual Chassis mode setting if it was previously enabled. You must include at least one of the supported modes that you want to disable with this option: `fabric`, `mixed`, or `network-port`.

The `request virtual-chassis mode mixed disable` command does not also automatically disable the mixed mode `ieee-clause-82` port mode option. To disable `ieee-clause-82` port mode on the device, you must include that option in the disable command as follows:

```
request virtual-chassis mode mixed ieee-clause-82 disable
```

fabric Set the device into fabric mode so it can participate as a member device in a VCF.

hgoe (EX4400-24X) Configure the QSFP28 ports as VCPs in HGoE mode.

local (Optional) Set the Virtual Chassis mode only on the member device where the command is issued.

member *member-id* (Optional) Set the Virtual Chassis mode on the specified member of the Virtual Chassis or VCF.

mixed <ieee-clause-82> Set the device into mixed mode so that the device can participate in a mixed Virtual Chassis or mixed VCF.

You must set mixed mode with the `ieee-clause-82` option on EX4300 switches that are not multigigabit models when mixing them with EX4300 multigigabit (EX4300-48MP) model switches in an EX4300 Virtual Chassis.

network-port (EX4400 switches only) Set an EX4400 switch into network port mode, which converts the default VCPs on the switch to network port mode so you can use them as network ports instead of VCPs.

reboot After applying the mode change specified by the other options, reboot the device automatically. You must reboot the device for any mode change to take effect.

Required Privilege Level

system-control

Sample Output

request virtual-chassis mode mixed

```
user@switch> request virtual-chassis mode mixed
```

Sample Output

request virtual-chassis mode fabric mixed reboot

```
user@switch> request virtual-chassis mode fabric mixed reboot
```

Sample Output

request virtual-chassis mode mixed (with IEEE Clause 82 mode for EX4300 switches mixed with EX4300 multigigabit switches in a Virtual Chassis)

```
user@switch> request virtual-chassis mode ieee-clause-82 mixed
```

Removing or Replacing a Member Switch of a Virtual Chassis Configuration

request virtual-chassis routing-engine master switch

IN THIS SECTION

- Syntax | 15466
- Description | 15466
- Options | 15467
- Required Privilege Level | 15467
- Sample Output | 15467

Release Information | 15468

Syntax

```
request virtual-chassis routing-engine master switch
<check>
```

Description

Change the primary role in an MX Series Virtual Chassis or EX9200 Virtual Chassis by switching the global roles of the primary router or switch and backup router or switch in the Virtual Chassis configuration. The `request virtual-chassis routing-engine master switch` command must be issued from the primary router or switch (VC-Pp).

(MX Series routers only) The local roles (`master` and `standby`, or `m` and `s`) of the Routing Engines in the Virtual Chassis primary router change after a global switchover, but the local roles of the Routing Engines in the Virtual Chassis backup router do not change. For example, the primary Routing Engine in the Virtual Chassis primary router (VC-Pp) becomes the standby Routing Engine in the Virtual Chassis backup router (VC-Bs) after the global switchover. By contrast, the primary Routing Engine in the Virtual Chassis backup router (VC-Bp) remains the primary Routing Engine in the Virtual Chassis primary router (VC-Pp) after the global switchover.

NOTE: Before you issue the `request virtual-chassis routing-engine master switch` command from the primary router or switch in the Virtual Chassis, make sure that the system configuration is synchronized between the primary and backup router or switch. If the configuration is not synchronized, or if you attempt to issue the `request virtual-chassis routing-engine master switch` command from the backup router or switch instead of from the primary router or switch, the device displays an error message and rejects the command.

If you issue the `request virtual-chassis routing-engine master switch` command when the Virtual Chassis is in a transition state (for example, the backup router or switch is disconnecting from the Virtual Chassis), the device does not process the command.

Options

check (Optional) Perform a check from the primary router or switch to determine whether the member routers or switches are ready for GRES from a database synchronization perspective, without initiating the GRES operation itself.

Required Privilege Level

system-control

Sample Output

request virtual-chassis routing-engine master switch (From Primary Router)

```
{master:member0-re0}
user@host> request virtual-chassis routing-engine master switch
Do you want to continue ? [yes,no] (no)
```

request virtual-chassis routing-engine master switch (Error When Configuration Not Synchronized)

```
{master:member0-re0}
user@host> request virtual-chassis routing-engine master switch
Error: mastership switch request NOT honored, backup not ready
```

request virtual-chassis routing-engine master switch (Error When Run from Backup Router)

```
{backup:member1-re0}
user@host> request virtual-chassis routing-engine master switch
error: Virtual Chassis member is not the protocol master
```

request virtual-chassis routing-engine master switch check (Ready for GRES)

```
{master:member0-re0}
user@host> request virtual-chassis routing-engine master switch check
Switchover Ready
```

request virtual-chassis routing-engine master switch check (Not Ready for GRES)

```
{master:member0-re0}
user@host> request virtual-chassis routing-engine master switch check
error: chassisd Not ready for mastership switch, try after 217 secs.
mastership switch request NOT honored, backup not ready
```

Release Information

Command introduced in Junos OS Release 11.2.

Option `check` introduced in Junos OS Release 12.2.

Syntax

```
request virtual-chassis vc-port (set | delete)
<fpc-slot fpc-slot> pic-slot pic-slot port port-number
interface interface-name
<member  | local>
```

member-id

Description

Set a port to operate as a Virtual Chassis port (VCP), or delete the VCP setting on a port. See Virtual Chassis Port Options for details on which ports you can set as VCPs on different switches. After setting a port as a VCP, you can't use the port for any other purpose unless you remove the VCP setting.

You can specify the port using the `interface` option or the `pic-slot` and `port` options.

If you don't include the `member` *`member-id`* option, this command defaults to setting the port as a VCP or deleting the VCP setting on the switch where you run the command. You can alternatively set the `local` option to ensure the command applies to the specified port on the local switch where you run it.

You might experience a temporary traffic disruption immediately after creating or deleting a user-configured VCP in an EX8200 Virtual Chassis.

Some switches have ports that are dedicated VCPs (you can only use them as VCPs and for no other purpose) or that are configured as VCPs by default (set as VCPs in the default factory configuration). You do not need to explicitly set those ports as VCPs to use them to interconnect the switch into a Virtual Chassis. See Virtual Chassis Port Options for details.

If you don't need a default-configured VCP to interconnect Virtual Chassis member switches, you can run this command with the `delete` option to remove the VCP setting and use the port as a regular uplink or network port. If you want to use the port as a VCP again later, then you need to run this command with the `set` option to reapply the VCP setting.

Special Behavior for VCPs on EX4400 Switches

On EX4400 switches, you don't use this command to convert ports on the switch into VCPs. EX4400 switches have default VCPs which are the only ports you can use as VCPs on the switch. These are the two 100-Gbps QSFP28 ports on the rear panel in PIC slot 1, which are set by default as four logical 50-Gbps VCP interfaces (vcp-255/1/0 through vcp-255/1/3). You can convert them into network ports by enabling network port mode on the switch (`request virtual-chassis mode network-port <reboot>`). In that case, to subsequently use the switch in a Virtual Chassis, you must disable network port mode (`request virtual-chassis mode network-port disable <reboot>`), which converts those ports back into VCPs. (Port mode changes apply to all VCPs on the switch,)

You can enter the `request virtual-chassis vc-port delete` command to disable these ports as VCPs, but, as mentioned above, that action doesn't convert them into network ports.

> **NOTE**: On EX4400 switches, if you use the `request virtual-chassis vc-port delete interface` *`interface-name`* command to disable logical VCP interface vcp-255/1/0, the switch disables both logical ports 0 and 1 (vcp-255/1/0 and vcp-255/1/1). Similarly, if you disable logical VCP interface vcp-255/1/2, that action disables both logical ports 2 and 3 (vcp-255/1/2 and vcp-255/1/3).

Options

set	Set a port as a VCP to convert an uplink or network port into a VCP.
delete	Delete the VCP setting on a port to convert a VCP back into an uplink or network port.
pic-slot *pic-slot*	Number of the PIC slot for the port on the switch.
port *port-number*	Number of the port that you want to enable or disable as a VCP.
interface *interface-name*	Interface name of the port that you want to enable or disable as a VCP. You can use this option to specify the port instead of using the `pic-slot` and `port` options.
member *member-id*	(Optional) Enable or disable the specified VCP on the specified member of the Virtual Chassis or VCF.
local	(Optional) Enable or disable the specified VCP on the local switch where you run the command.

Required Privilege Level

system-control

Sample Output

request virtual-chassis vc-port set pic-slot 1 port 0

```
user@switch> request virtual-chassis vc-port set pic-slot 1 port 0
```

To check the results of this command, use the "show virtual-chassis vc-port" on page 27681 command.

request virtual-chassis vc-port set pic-slot 1 port 1 member 3

```
user@switch> request virtual-chassis vc-port set pic-slot 1 port 1 member 3
```

To check the results of this command, use the "show virtual-chassis vc-port" on page 27681 command.

request virtual-chassis vc-port delete pic-slot 1 port 1 member 3

```
user@switch> request virtual-chassis vc-port delete pic-slot 1 port 1 member 3
```

To check the results of this command, use the "show virtual-chassis vc-port" on page 27681 command.

Release Information

Command introduced in Junos OS Release 9.0.

Option `fpc-slot` introduced in Junos OS Release 10.4 for EX Series switches.

request virtual-chassis vc-port (Dedicated VCP)

IN THIS SECTION

- Syntax | 15472
- Description | 15472
- Options | 15472
- Additional Information | 15473
- Required Privilege Level | 15473
- Sample Output | 15473
- Release Information | 15474

Syntax

```
request virtual-chassis vc-port set interface vcp-interface-name
<member member-id> <disable>
```

Description

Disable or enable a Virtual Chassis port (VCP) on a dedicated VCP.

Configure a Gigabit Ethernet link on an EX8200 switch as a VCP in an EX8200 Virtual Chassis. You can use this command only to configure a link between two EX8200 member switches as a VCP link; all other links in an EX8200 Virtual Chassis are automatically VCP links.

Options

interface ***vcp-interface-name***

Name of the interface to enable or disable.

If you omit **member** ***member-id*** in an EX4200 Virtual Chassis, EX4500 Virtual Chassis, EX4550 Virtual Chassis, mixed Virtual Chassis, this command defaults to disabling or

enabling the dedicated VCP on the switch where the command is issued. The dedicated VCPs are enabled in the factory default configuration.

member *member-id*
(Optional on EX4200, EX4500, and EX4550 switches; required on EX8200 switches) Enable or disable the specified VCP on the specified member of the Virtual Chassis configuration.

This option must be specified when using this command to configure a VCP link between two EX8200 switches.

disable
(Optional) Disable the specified VCP. If you omit this keyword, the command enables the dedicated VCP.

Additional Information

Required Privilege Level

system-control

Sample Output

request virtual-chassis vc-port set interface vcp-0 disable (EX4200 Virtual Chassis)

```
user@switch> request virtual-chassis vc-port set interface vcp-0 disable
```

To check the results of this command, use the "show virtual-chassis vc-port" on page 27681 command.

request virtual-chassis vc-port set fpc-slot 4 pic-slot 0 port 2 member 1 (EX8200 Virtual Chassis)

```
user@external-routing-engine>
 request virtual-chassis vc-port set fpc-slot 4 pic-slot 0 port 2 member 1
```

To check the results of this command, use the "show virtual-chassis vc-port" on page 27681 command.

request virtual-chassis vc-port set interface vcp-0 member 3 disable (EX8200 Virtual Chassis)

```
user@external-routing-engine> request virtual-chassis vc-port set interface vcp-0 member 3
disable
```

To check the results of this command, use the "show virtual-chassis vc-port" on page 27681 command.

Release Information

Command introduced in Junos OS Release 9.0.

RELATED DOCUMENTATION

request virtual-chassis vc-port delete (MX Series Virtual Chassis)

IN THIS SECTION

- Syntax | 15475
- Description | 15475
- Options | 15475
- Required Privilege Level | 15476
- Sample Output | 15476
- Release Information | 15476

Syntax

```
request virtual-chassis vc-port delete fpc-slot fpc-slot-number pic-slot pic-slot-number port
port-number
<(local | member member-id)>
```

Description

Remove (**delete**) a Virtual Chassis port from a member router in an MX Series Virtual Chassis configuration. After a Virtual Chassis port is created, it is renamed **vcp-*slot/pic/port***, and is no longer available for configuration as a standard network port. After you remove a Virtual Chassis port, it becomes available to the global configuration and can again function as a standard network port.

> **NOTE**: If the member ID has not been set on the router where you issue the `request virtual-chassis vc-port delete` command, the software prevents the removal of the Virtual Chassis port on the router. To set the member ID, use the `request virtual-chassis member-id set` command.

Options

fpc-slot *fpc-slot-number*

Number of the Flexible PIC Concentrator (FPC) slot on which the Virtual Chassis port resides. The slot number corresponds to the Modular Port Concentrator (MPC) slot number. Replace ***fpc-slot-number*** with a value appropriate for your router:

- MX960 router—0 through 11.
- MX480 router—0 through 5.
- MX240 router—0 through 2.

pic-slot *pic-slot-number*

Number of the PIC slot on which the Virtual Chassis port resides. Replace ***pic-slot-number*** with a value in the range 0 through 3.

port *port-number*

Number of the port on the PIC on which the Virtual Chassis port resides. Replace ***port-number*** with a value appropriate for your PIC.

local

(Optional) Delete the Virtual Chassis port on the member router on which you are issuing the command. This is the default behavior if you do not specify the **local** or **member** options.

member *member-id* (Optional) Numeric value that identifies the remote Virtual Chassis member on which you want to delete the Virtual Chassis port. Replace ***member-id*** with the value 0 or 1.

Required Privilege Level

system-control

Sample Output

request virtual-chassis vc-port delete (Remove vcp-3/2/1)

```
user@host> request virtual-chassis vc-port delete fpc-slot 3 pic-slot 2 port 1
vc-port successfully deleted
```

Release Information

Command introduced in Junos OS Release 11.2.

RELATED DOCUMENTATION

Example: Deleting a Virtual Chassis Configuration for MX Series 5G Universal Routing Platforms

request virtual-chassis vc-port diagnostics optics

IN THIS SECTION

- Syntax | 15477
- Description | 15477
- Required Privilege Level | 15477
- Sample Output | 15477
- Release Information | 15477

Syntax

```
request virtual-chassis vc-port diagnostics optics
```

Description

Run a digital optical monitoring (DOM) scan on the optical ports configured as Virtual Chassis ports (VCPs).

Enter the `show virtual-chassis vc-port diagnostics optics` command to view the results of the diagnostic scan.

On certain EX Series switches, you must enter the `request virtual-chassis vc-port diagnostics optics` command to run a diagnostic scan before you can gather the `show virtual-chassis vc-port diagnostics optics` output.

Required Privilege Level

system-control

Sample Output

request virtual-chassis vc-port diagnostics optics

```
user@switch> request virtual-chassis vc-port diagnostics optics
fpc0:
--------------------------------------------------------------------------
vc-port Diagnostics Optics Done
```

Release Information

Command introduced in Junos OS Release 13.2X50-D10.

RELATED DOCUMENTATION

show virtual-chassis vc-port diagnostics optics | 27688

request virtual-chassis vc-port set (MX Series Virtual Chassis)

IN THIS SECTION

- Syntax | 15478
- Description | 15478
- Options | 15479
- Required Privilege Level | 15479
- Sample Output | 15480
- Release Information | 15480

Syntax

```
request virtual-chassis vc-port set fpc-slot fpc-slot-number pic-slot pic-slot-number port port-number
<(local | member member-id)>
```

Description

Create (**set**) a Virtual Chassis port on an MX Series router through which the router connects to other member routers in the Virtual Chassis. You can create Virtual Chassis ports only on Modular Port Concentrator/Modular Interface Card (MPC/MIC) network ports on MX Series routers.

After a Virtual Chassis port is created, it is renamed **vcp-*slot/pic/port***, and is no longer available for configuration as a standard network port. Virtual Chassis ports can be used only to interconnect the MX Series routers in the Virtual Chassis.

NOTE: If the member ID has not been set on the router where you issue the `request virtual-chassis vc-port set` command, the software prevents the creation of the Virtual Chassis port on the router. To set the member ID, use the `request virtual-chassis member-id set` command.

Options

fpc-slot ***fpc-slot-number***

Number of the Flexible PIC Concentrator (FPC) slot on which the Virtual Chassis port resides. The slot number corresponds to the Modular Port Concentrator (MPC) slot number. Replace ***fpc-slot-number*** with a value appropriate for your router:

- MX960 router—0 through 11.
- MX480 router—0 through 5.
- MX240 router—0 through 2.

When you issue the `show interfaces` command on a member router in an MX Series Virtual Chassis, the FPC slot number displayed in the command output reflects the FPC slot numbering and offset used in the Virtual Chassis instead of the physical slot number where the FPC is actually installed. The router with member ID 0 in the Virtual Chassis uses FPC slot numbers 0 through 11 with no offset, and the router with member ID 1 uses FPC slot numbers 12 through 23, with an offset of 12. For example, a 10-Gigabit Ethernet interface that appears as **xe-14/2/2** (FPC slot 14, PIC slot 2, port 2) in the `show interfaces` command is actually interface **xe-2/2/2** (FPC slot 2, PIC slot 2, port 2) on member ID 1 after deducting the FPC slot numbering offset of 12 for member ID 1.

pic-slot ***pic-slot-number***

Number of the PIC slot on which the Virtual Chassis port resides. Replace ***pic-slot-number*** with a value in the range 0 through 3.

port ***port-number***

Number of the port on the PIC on which the Virtual Chassis port resides. Replace ***port-number*** with a value appropriate for your PIC.

local

(Optional) Set the Virtual Chassis port on the member router on which you are issuing the command. This is the default behavior if you do not specify the **local** or **member** options.

member ***member-id***

(Optional) Numeric value that identifies the remote Virtual Chassis member on which you want to create the Virtual Chassis port. Replace ***member-id*** with the value 0 or 1.

Required Privilege Level

system-control

Sample Output

request virtual-chassis vc-port set (No Existing Network Port)

```
user@host> request virtual-chassis vc-port set fpc-slot 1 pic-slot 1 port 0
vc-port successfully set
```

request virtual-chassis vc-port set (Existing Network Port Converted)

```
user@host> request virtual-chassis vc-port set fpc-slot 2 pic-slot 1 port 1
Port conversion initiated, use “show virtual chassis vc-port” to verify
```

request virtual-chassis vc-port set (On Local Router)

```
user@host> request virtual-chassis vc-port set fpc-slot 2 pic-slot 1 port 3 local
vc-port successfully set
```

request virtual-chassis vc-port set (On Remote Member Router 1)

```
user@host> request virtual-chassis vc-port set fpc-slot 5 pic-slot 3 port 10 member 1
vc-port successfully set
```

Release Information

Command introduced in Junos OS Release 11.2.

Guidelines for Configuring Virtual Chassis Ports

request virtual-network-functions

IN THIS SECTION

- Syntax | 15481
- Description | 15481
- Options | 15481
- Required Privilege Level | 15482
- Release Information | 15482

Syntax

`request virtual-network-functions` *`vnf-name`* `(add-image | all-servers | delete-image | force | restart | server | start | stop)`

Description

Start, stop or restart the VNFs. Also, you can add or remove the base image.

> **NOTE**: You can issue these commands either on both the servers (server0 and server1) or on one specific server.

Options

vnf-name	Name of the VNF.
add-image	Add the base image to the VNF repository.
all-servers	Issue the command on both the servers.
delete-image	Delete the base image from the VNF repository.
force	Overwrite the image that was added earlier (example: `request virtual-network-functions` *`vnf-name`* `add-image` *`new-image-name`* `force`). The `force` option is also used with `delete-image` command to perform a cleanup in case, for example, you abruptly stopped an earlier `add-image` process by pressing Ctrl-C.

restart Restart the VNF specified.

server Issue the command on a specific server. Applicable value is `0` or `1`.

start Start the VNF.

stop Stop the VNF.

Required Privilege Level

View

Release Information

Command introduced in Junos OS Release 17.2R1.

The `force` option is available from Junos OS Release 17.4R1.

RELATED DOCUMENTATION

Generic Guidelines for Using JDM Server Commands

show virtual-network-functions (Junos Node Slicing) | **27728**

request server authenticate-peer-server | **14901**

request vmhost cleanup

IN THIS SECTION

- Syntax | **15483**
- Description | **15483**
- Options | **15483**
- Required Privilege Level | **15484**
- Output Fields | **15484**
- Release Information | **15484**

Syntax

```
request vmhost cleanup
invoke-on;
(re0 | re1);
routing engine;
```

Description

Clean up temporary files, crash generated files, and log files located in the **/var/tmp**, **/var/crash**, and **/var/log directories respectively** on the host OS.

> **NOTE**: You can clean up files of any format in the **/var/tmp** and **/var/crash** location. However, you can cleanup only the .gz format files in the **/var/log/** location.

Options

none—Clean up temporary files, crash generated files, and log files located in the **/var/tmp**, **/var/crash**, and **/var/log directories** on the host OS running on the Routing Engine on the local Virtual Chassis member.

invoke-on

(Optional) Clean up temporary files, crash generated files, and log files on all the Routing Engines or the other Routing Engine.

Clean up files in **/var/tmp**, **/var/crash**, and **/var/log** on the host OS running on a router that has dual Routing Engines. You can use the `all-routing-engine` option to clean up the files in these directories on the host OS running on all the Routing Engines or the `other-routing-engine` option to clean up the files in these directories on the host OS running on the other Routing Engine. If you issue the command from the primary Routing Engine, the backup Routing Engine is referred to as the other Routing Engine.

re0 | re1

(Optional) On devices that support dual or redundant Routing Engines, clean up files in **/var/tmp**, **/var/crash**, and **/var/log** on the host OS running on the Routing Engine in slot 0 (`re0`) or the Routing Engine in slot 1 (`re1`).

> **NOTE**: The QFX10002-60C and PTX10002-60C devices do not have primary and backup routing engines.

routing-engine (Optional) Specify the Routing Engine for which the files in **/var/tmp**, **/var/crash**, and **/var/log** on the host OS are to be cleaned up. The following options are available:

- `backup`—Backup Routing Engine.
- `both`—Primary and backup Routing Engines.
- `local`—Routing Engine on the local Virtual Chassis member.
- `master`—Primary Routing Engine.
- `other`—If you issue the command from the primary Routing Engine, the backup Routing Engine is referred to as the other Routing Engine.

Required Privilege Level

maintenance

Output Fields

When you enter this command, you are provided feedback on the status of your request.

Release Information

Command introduced in Junos OS Release 15.1F3.

NOTE: PTX3000 router supports the Routing and Control Board, RCBPTX.

- Description | 15499
- Required Privilege Level | 15499
- Release Information | 15499

Syntax

```
request vmhost jdm delete
```

Description

Uninstalls the Juniper Device Manager (JDM). This command is applicable to in-chassis Junos node slicing.

Required Privilege Level

maintenance

Release Information

Command introduced in Junos OS Release 19.1R1.

RELATED DOCUMENTATION

Generic Guidelines for Using JDM Server Commands

show virtual-network-functions (Junos Node Slicing) | 27728

request server authenticate-peer-server | 14901

request vmhost jdm login (In-Chassis Model)

IN THIS SECTION

- Syntax | 15500
- Description | 15500
- Required Privilege Level | 15500
- Sample Output | 15500
- Release Information | 15501

Syntax

```
request vmhost jdm login
```

Description

Logs in to the Juniper Device Manager (JDM). This command is applicable to in-chassis Junos node slicing.

NOTE: To log in to JDM, you must be a root user.

Required Privilege Level

maintenance

Sample Output

request vmhost jdm login

```
root@router> request vmhost jdm login

***************************************************************************
* The Juniper Device Manager (JDM) must only be used for orchestrating the *
* Virtual Machines for Junos Node Slicing *
* *
```

```
* Host Linux Distro: Wind River Linux *
* JDM Version: jns-jdm-vmhost-19.1-20181003.dev.common.0.x86_64 *
* Free Disk Space on JDM's root-fs ("/"): 125081(MiB) *
***************************************************************************
Last login: Thu Oct 4 15:26:30 2018 from 192.168.1.1
```

Release Information

Command introduced in Junos OS Release 19.1R1.

- Syntax | **15501**
- Description | **15501**
- Required Privilege Level | **15502**
- Sample Output | **15502**
- Release Information | **15502**

Syntax

```
request vmhost jdm start
```

Description

Starts the Juniper Device Manager (JDM). This command is applicable to in-chassis Junos node slicing.

Required Privilege Level

maintenance

Sample Output

request vmhost jdm start

```
user@router> request vmhost jdm start
Starting JDM
Starting jdm: Domain jdm defined from
/vm/vm/iapps/jdm//install/juniper/lxc/jdm/current/config/jdm.xml
Domain jdm started
```

Release Information

Command introduced in Junos OS Release 19.1R1.

Syntax

```
request vmhost jdm stop
```

Description

Stops the Juniper Device Manager (JDM). This command is applicable to in-chassis Junos node slicing.

Required Privilege Level

maintenance

Release Information

Command introduced in Junos OS Release 19.1R1.

RELATED DOCUMENTATION

Generic Guidelines for Using JDM Server Commands

show virtual-network-functions (Junos Node Slicing) | **27728**

request server authenticate-peer-server | **14901**

request vmhost local-file-copy

IN THIS SECTION

- Syntax | **15504**
- Description | **15504**
- Options | **15504**
- Additional Information | **15504**
- Required Privilege Level | **15504**
- Sample Output | **15505**
- Release Information | **15505**

Syntax

```
request vmhost local-file-copy source source_path destination destination_path;
```

Description

Copy a file or a directory present under **/var/public/** directory structure on the hypervisor to a different name under **/var/public/** directory structure.

Options

- source *source-path*—Name of the source path from which the file is to be copied.
- destination*destination-path*—Name of the destination path to which the file is copied.

Additional Information

Consider the following guidelines while creating a local path.

- Both paths should be under **/var/public/** directory
- Avoid special characters. You can include alphanumeric characters, hyphen, underscore, dot, and asterisk.
- Avoid relative path components **..** and **/./**
- Avoid ending the path with **/.**

Following are the examples of a path:

- **/var/public/sanity_packages**
- **/var/public/sanity_packages/readme.txt**
- **/var/public/12-hours.data**

Required Privilege Level

Maintenance

Sample Output

request vmhost local-file-copy (To copy a directory)

```
user@host> request vmhost local-file-copy source /var/public/sanity_packages destination /var/
public/new_sanity_packages
'/var/public/sanity_packages' -> '/var/public/new_sanity_packages'
'/var/public/sanity_packages/centos-linux-1.img.gz' -> '/var/public/new_sanity_packages/centos-
linux-1.img.gz'
'/var/public/sanity_packages/vnf_test_pkg.tar.gz' -> '/var/public/new_sanity_packages/
vnf_test_pkg.tar.gz'
'/var/public/sanity_packages/readme.txt' -> '/var/public/new_sanity_packages/readme.txt'
```

request vmhost local-file-copy (To copy a file specifying the destination file name)

```
user@host> request vmhost local-file-copy source
/var/public/sanity_packages/readme.txt destination
/var/public/new_sanity_packages/new_readme.txt
'/var/public/sanity_packages/readme.txt' ->
'/var/public/new_sanity_packages/new_readme.txt'
```

request vmhost local-file-copy (To copy a file specifying the destination directory)

```
user@host> request vmhost local-file-copy source
 /var/public/sanity_packages/readme.txt destination
/var/public/new_sanity_packages/
'/var/public/sanity_packages/readme.txt' ->
'/var/public/new_sanity_packages/readme.txt'
```

Release Information

Command introduced in Junos OS Release 24.2R1 for NFX150, NFX250, and NFX350 devices.

request vmhost mode

IN THIS SECTION

- Syntax | 15506
- Description | 15506
- Required Privilege Level | 15507
- Sample Output | 15507
- Release Information | 15507

Syntax

```
request vmhost mode [compute | hybrid | throughput | mode-name]
```

Description

Select the operational mode of the device from a pre-defined list of modes (compute, hybrid, or throughput) or specify a *mode-name* for a custom mode.

NOTE:

- Starting from Junos OS Release 19.3R1, if the same physical CPU is used for both VNFs and the Junos OS or device components, the request to change the mode fails and an error message is displayed. For example:

  ```
  root> request vmhost mode throughput
  error: Mode cannot be changed; Reason: Reserved CPUs conflict with VNF cpu
  pinnings: 3
  ```

- When you upgrade the software image that has a VNF CPU conflict to Junos OS Release 19.3R1 by using the CLI upgrade option, the upgrade succeeds and the VNF

configuration is applied. The VNF CPU conflict is reported by JDM only if you issue a `commit` command. You must modify the VNF configurations accordingly.

Required Privilege Level

maintenance

Sample Output

request vmhost mode compute

```
user@host> request vmhost mode compute
warning: Device will be rebooted to change the mode from hybrid to compute
Do you want to continue? [yes,no] (no)
```

Release Information

The `request vmhost mode` command is introduced in Junos OS Release 19.1R1.

The `request vmhost mode` *`mode-name`* command is introduced in Junos OS Release 21.1R1 for NFX250 NextGen and NFX350 devices.

request-vmhost-power-cycle-cb

IN THIS SECTION

- Syntax | 15508
- Description | 15508
- Required Privilege Level | 15508
- Sample Output | 15508
- Release Information | 15516

Syntax

```
request vmhost power-cycle-cb
```

Description

Initiates the power cycle for the Chassis.

Required Privilege Level

maintenance

Sample Output

request vmhost power-cycle-cb

```
user@host> request vmhost power-cycle-cb
Power cycle the Chassis/CB ? [yes,no] (no) yes

Initiating vmhost power-cycle-cb...
warning: Initiating Junos shutdown...

Release Information

request-vmhost-power-cycle-re

IN THIS SECTION

- Syntax | 15516
- Description | 15516
- Required Privilege Level | 15516
- Sample Output | 15516
- Release Information | 15524

Syntax

```
request vmhost power-cycle-cb
```

Description

Initiates the power cycle for the Routing Engine.

Required Privilege Level

maintenance

Sample Output

request vmhost power-cycle-re

```
user@host> request vmhost power-cycle-re
Power cycle the RE ? [yes,no] (no) yes

Initiating vmhost power-cycle...
```

```
warning: Initiating Junos shutdown...

Release Information

request vmhost power-off

IN THIS SECTION

- Syntax | 15525
- Description | 15525
- Options | 15525
- Required Privilege Level | 15526
- Sample Output | 15526
- Release Information | 15526

Syntax

```
request vmhost power-off
<other routing-engine>
```

Description

Power off the Routing Engine on which Junos OS and the host OS are running. In a PTX3000, the Routing and Control Board is powered off.

NOTE: The QFX10002-60C and PTX10002-60C devices do not have primary and backup routing engines.

Options

none—Power off the Routing Engine immediately.

other-routing-engine (Optional) Power off the other Routing Engine on which the Junos OS and the host OS are running. For example, if you issue the command from the primary Routing Engine, the backup Routing Engine is powered off. Similarly, if you issue the command from the backup Routing Engine, the primary Routing Engine is powered off.

Required Privilege Level

maintenance

Sample Output

request vmhost power-off

```
request vmhost power-off
```

Release Information

Command introduced in Junos OS Release 15.1F3.

> **NOTE**: PTX3000 router supports the Routing and Control Board, RCBPTX.

RELATED DOCUMENTATION

request system power-off

request vmhost power-off (NFX Series)

IN THIS SECTION

- Syntax | 15527
- Description | 15527
- Required Privilege Level | 15527
- Sample Output | 15527
- Release Information | 15527

Syntax

```
request vmhost power-off
```

Description

Shut down the Junos OS software and the host OS.

Required Privilege Level

maintenance

Sample Output

request vmhost power-off

```
user@host> request vmhost power-off
Power-off the vmhost ? [yes,no] (no) yes

Initiating vmhost shutdown...  ok
Initiating Junos shutdown...  shutdown: [pid 3884]
Shutdown NOW!
ok

*** FINAL System shutdown message from root@host ***

System going down IMMEDIATELY
...
...
```

Release Information

Command introduced in Junos OS Release 18.1R1.

NOTE: `request vmhost power-on` is not supported on NFX150 and NFX250 (NG) devices.

request vmhost power-on

IN THIS SECTION

- Syntax | 15528
- Description | 15528
- Options | 15528
- Required Privilege Level | 15528
- Sample Output | 15529
- Release Information | 15529

Syntax

```
request vmhost power-on other-routing-engine
```

Description

Power on the Routing Engine on which Junos OS and the host OS are running. In a PTX3000, the Routing and Control Board is powered on.

Options

other-routing-engine Power on the other Routing Engine on which the Junos OS and the host OS are running. For example, if you issue the command from the primary Routing Engine, the backup Routing Engine is powered on. Similarly, if you issue the command from the backup Routing Engine, the primary Routing Engine is powered on.

> **NOTE**: The QFX10002-60C and PTX10002-60C devices do not have primary and backup routing engines.

Required Privilege Level

maintenance

Sample Output

request vmhost power-on

```
user@host> request vmhost power-on other-routing-engine
Routing Engine 1 power-on initiated, use "show chassis routing-engine" to verify
```

Release Information

Command introduced in Junos OS Release 15.1F3.

NOTE: PTX3000 router supports the Routing and Control Board, RCBPTX.

RELATED DOCUMENTATION

request vmhost power-off | 15525

request vmhost reboot | 15529

request vmhost reboot

IN THIS SECTION

- Syntax | 15530
- Description | 15530
- Options | 15530
- Required Privilege Level | 15531
- Sample Output | 15531
- Release Information | 15531

Syntax

```
request vmhost reboot
<disk1>
<disk2>
<network>
<re0 | re1>
<routing engine>
<usb>
```

Description

Reboot both the Junos OS and the host OS running on the device.

Options

none—Reboot the device software immediately.

disk1 (Optional) Reboot both Junos OS and the host OS on the Routing Engine and boot the Routing Engine from the primary disk.

disk2 (Optional) Reboot both Junos OS and the host OS on the Routing Engine and boot the Routing Engine from backup disk.

network (Optional) Reboot both Junos OS and the host OS on the Routing Engine and boot the Routing Engine from network by using the PXE boot method.

re0 | re1 (Optional) On routers that support dual or redundant Routing Engines, reboot both Junos OS and the host OS on the Routing Engine in slot 0 (`re0`) or on the the Routing Engine in slot 1 (`re1`).

routing-engine (Optional) Specify the Routing Engine on which Junos OS and the host OS are to be rebooted. The following options are available:

> **NOTE**: The QFX10002-60C and PTX10002-60C devices do not have primary and backup routing engines.

- `backup`—Backup Routing Engine.
- `both`—Both Routing Engines.

- `local`—Routing Engine on the local Virtual Chassis member.
- `master`—Primary Routing Engine.
- `other`—If you issue the command from the primary Routing Engine, the backup Routing Engine is referred to as the other Routing Engine.

usb (Optional) Reboot both Junos OS and the host OS on the Routing Engine using the USB installation media.

Required Privilege Level

maintenance

Sample Output

request vmhost reboot

```
request vmhost reboot
<disk1>
<disk2>
<in>
<network>
<usb>
```

Release Information

Command introduced in Junos OS Release 15.1F3.

NOTE: PTX3000 router supports the Routing and Control Board, RCBPTX.

Release Information

Command introduced in Junos OS Release 18.1R1.

request vmhost remote-file-copy

IN THIS SECTION

- Syntax | 15535
- Description | 15535
- Options | 15535
- Additional Information | 15536
- Required Privilege Level | 15537
- Sample Output | 15537
- Release Information | 15539

Syntax

```
request vmhost remote-file-copy
                 interface {
                       (in-band | out-of-band);
                       }
                   source source-path;
                   destination destination-path;
```

Description

Enable remote file copy between the hypervisor and a remote fileserver. The configuration allows creating an external network interface directly on the hypervisor and associating an IPv4 address with it.

The remote file copy feature allows upload or download operations from or into the NFX device. These operations are initiated from the NFX device, not from the remote fileserver.

Options

- in-band—Enable external network access through one of the front panel revenue ports.
- out-of-band—Enable external network access through the front panel management interface.

- source *source-path*—Name of the source path from which the file is to be copied. The source path should refer to a specific filename, not a directory, and without any wild cards. If the *source-path* is local, the file-copy is an upload operation. If the *source-path* is remote, the file-copy is a download operation.
- destination*destination-path*—Name of the destination path to which the host file is copied. The destination path must refer to a specific filename.

Additional Information

Either *source-path* or *destination-path* must be remote while the other should be local. Consider the following guidelines while creating a local path:

- Local path should refer to a file under **/var/public/** directory.
- Avoid special characters. You can include alphanumeric characters, hyphen, underscore, and dot.
- Avoid relative path components **..** and **/./**
- Avoid ending the path with **/.**

Following are the examples of a local path:

- **/var/public/myfile**
- **/var/public/mydir/my_file**
- **/var/public/12-hours.data**

Consider the following guidelines while creating a local path:

- A remote path must be in the following format:
  [<remote_user>[:<remote_user_pwd>]@]<protocol>:// <remote_ip>[:<remote_port>]:<remote_path>

  The protocols supported are, SCP, HTTP, HTTPS, and FTP.

- `remote_user` is optional, depending on protocol and the remote fileserver configuration.

  For example, `remote_user` is required when scp protocol is used whereas `remote_user` is unnecessary when HTTP protocol is used.

- Depending on the protocol and the remote fileserver configuration, when `remote_user` is specified, you might have to specify `remote_user_pwd`.

  For example, when ftp is used, username and password are required.

- `remote_port` is optional and could be skipped if the remote fileserver is reachable on a standard port for the specified protocol.

Following are the examples of a remote path:

```
user@scp://10.10.10.2:22:/home/user/myfile
user@scp://10.10.10.2:/home/user/myfile
http://10.10.10.2:80:/myfile
https://10.10.10.2:80:/myfile
user:user@ftp://10.10.10.2:21:/home/user/myfile
user@ftp://10.10.10.2:21:/home/user/myfile
```

Required Privilege Level

Maintenance

Sample Output

request vmhost remote-file-copy (To upload a file from an NFX device to remote fileserver using an in-band interface and scp protocol, with user interaction)

```
user@host> request vmhost remote-file-copy interface in-band source /var/public/1G.dat

Release Information

Command introduced in Junos OS Release 24.2R1 for NFX150, NFX250, and NFX350 devices.

request vmhost snapshot

IN THIS SECTION

- Syntax | 15539
- Description | 15540
- Options | 15540
- Required Privilege Level | 15541
- Sample Output | 15541
- Release Information | 15542

Syntax

```
request vmhost snapshot
<partition>
<re0 | re1>
<recovery>
<routing-engine>
```

Description

Create a recovery snapshot of the currently running and active file system partitions on the backup disk to recover the primary disk in case of failure.

On the device, back up the snapshot of the host OS image along with the Junos OS image. In case of failure of the primary disk, you can boot from the image available in the backup disk and then recover the primary disk with the snapshot created using the `recovery` option.

Options

none—Create a snapshot from the current disk to the target disk without partitioning the target disk. Contents on target disk is lost.

`partition` (Optional) Create a snapshot from the current disk to target disk and partition the target disk. Contents on the target disk are lost

re0 | re1 (Optional) Create a snapshot from the current disk to target disk and partition the target disk on Routing Engine in slot 0 (`re0`) or on the Routing Engine in slot 1 (`re1`). The snapshot is taken without partitioning the target disk on corresponding Routing Engines. Contents on the target disk on the Routing Engines are lost.

For PTX1000 routers, since there is only one RE, re0|re1 is not supported.

> **NOTE**: The QFX10002-60C and PTX10002-60C devices do not have primary and backup routing engines.

recovery (Optional) Recover the primary disk from the snapshot content stored in the backup disk. This option is applicable only when the Routing engine is booted from backup disk. Contents in the primary disk are lost.

routing-engine (Optional) Specify the Routing Engine on which the snapshot is to be created. The following options are available:

- `backup`—Backup Routing Engine.
- `both`—Both Routing Engines.
- `local`—Routing Engine on the local Virtual Chassis member.
- `master`—Primary Routing Engine.
- `other`—Other Routing Engine.

Required Privilege Level

maintenance

Sample Output

request vmhost snapshot

```
user@host> request vmhost snapshot
warning: Existing data on the target may be lost
Proceed ? [yes,no] (no) yes

warning: Proceeding with vmhost snapshot
Current root details,           Device sda, Label: jrootb_P, Partition: sda4
Snapshot admin context from current boot disk to target disk ...
Proceeding with snapshot on secondary disk
Mounting device in preparation for snapshot...
Cleaning up target disk for snapshot ...
Creating snapshot on target disk from current boot disk ...
Snapshot created on secondary disk.
Software snapshot done
```

request vmhost snapshot recovery

```
user@host> request vmhost snapshot recovery
warning: Existing data on the target may be lost
Proceed ? [yes,no] (no) yes

warning: Proceeding with vmhost snapshot
Current root details,           Device sdb, Label: jrootb_S, Partition: sdb4
Snapshot admin context from current boot disk to target disk ...
Proceeding with snapshot on primary disk
Mounting device in preparation for snapshot...
Cleaning up target disk for snapshot ...
Creating snapshot on target disk from current boot disk ...
Primary disk is recovered now. Please issue "request vmhost reboot" to boot from the primary
disk.
Software snapshot done
```

Release Information

Command introduced in Junos OS Release 15.1F3.

NOTE: PTX3000 router supports the Routing and Control Board, RCBPTX.

request vmhost software add

IN THIS SECTION

- MX Series | 15544
- PTX Series | 15544
- Description | 15544
- Options | 15545
- Additional Information | 15546
- Required Privilege Level | 15547
- Sample Output | 15547
- Release Information | 15547

MX Series

```
request vmhost software add package-name
<no-validate>
<re0 | re1>
<reboot>
<set [package-names]>
```

PTX Series

```
request vmhost software add package-name
<in>
<log_collector.sh>
<no-validate>
<reboot>
<set [package-names]>
<unlink>
<upgrade-to-model>
```

Description

Install Junos OS and host software packages on the device.

For installing the host software as well as Junos OS, specify the package name **junos-vmhost-install-*x*.tgz** in the `request vmhost software add` command. Junos OS installation alone can be achieved by specifying the regular package name **junos-install-*x*.tgz** in the `request system software add` command. However, installation using the vmhost package is recommended as it upgrades both the host software and Junos OS.

To upgrade to Junos OS Release 21.2R1, you must include the `no-validate` option when using this command to install the package.

> **NOTE**: You must load the PTX1000, PTX10008, PTX10016, PTX10002-60C, and QFX10002-60C devices only with **junos-vmhost-install-*x*.tgz** package using the `request vmhost software add` command. The **junos-vmhost-install-*x*.tgz** package upgrades both the host software and Junos OS. The PTX1000, PTX10008, PTX10016, PTX10002-60C, and QFX10002-60C devices do not support Junos only upgrade. If you try to load Junos only

image, then these devices go down or vmhost commands do not work or the device state is unpredictable.

Options

none—Install Junos OS and host software packages on the Routing Engine on the local Virtual Chassis member.

package-name Location from which the software package or bundle is to be installed. For example:

- **/var/tmp/*package-name***—For a software package or bundle that is being installed from a local directory on the device.
- ***protocol://hostname/pathname/package-name***—For a software package or bundle that is to be downloaded and installed from a remote location. Replace ***protocol*** with one of the following:
  - **ftp**—File Transfer Protocol (FTP).
    Use **ftp://*hostname/pathname/package-name***. To specify authentication credentials, use **ftp://<*username*>:<*password*>@*hostname/pathname/package-name***. To have the system prompt you for the password, specify `prompt` in place of the password. If a password is required, and you do not specify the password or `prompt`, an error message is displayed.
  - **http**—Hypertext Transfer Protocol (HTTP).
    Use **http://*hostname/pathname/package-name***. To specify authentication credentials, use **http://<*username*>:<*password*>@*hostname/pathname/package-name***. If a password is required and you omit it, you are prompted for it.
  - **scp**—Secure Copy Protcol (SCP)(not available for limited editions).
    Use **scp://*hostname/pathname/package-name***. To specify authentication credentials, use **scp://<*username*>:<*password*>@*hostname/pathname/package-name***.

NOTE:

- The ***pathname*** in the protocol is the relative path to the user's home directory on the remote system and not the root directory.

- Do not use the **scp** protocol in the `request vmhost software add` command to download and install a software package or bundle from a remote location. The software upgrade is handled by the mgd process that does not support SCP.

  To install a software package or bundle from a remote location:

  1. Use the `file copy` command to copy the software package or bundle from the remote location to the **/var/tmp** directory on the hard disk:
     file copy scp:// *source/ package-name* /var/tmp
  2. Install the software package or bundle by using the `request vmhost software add` command:
     request vmhost software add /var/tmp/*package-name*

no-validate (Optional) When loading a software package or bundle with a different release, suppress the default behavior of the `validate` option.

To upgrade to Junos OS Release 21.2R1, you must include the `no-validate` option when using this command to install the package.

re0 | re1 (Optional) Load a software package or bundle on the Routing Engine in slot 0 (`re0`) or the Routing Engine in slot 1 (`re1`).

> **NOTE**: The option `re1` is not supported on the PTX1000 Packet Transport Router.

reboot (Optional) After adding the software package or bundle, reboot the system.

set [*package-names*] (Optional)

Additional Information

Before upgrading the software on the device, when you have a known stable system, issue the `request vmhost snapshot` command to back up the software. After you have upgraded the software on the device and are satisfied that the new package or bundle is successfully installed and running, issue the `request vmhost snapshot` command again to back up the new software to the backup disk.

After you run the `request vmhost snapshot` command, you cannot return to the previous version of the snapshot, because the previous snapshot is replaced by the new snapshot.

Before installing software on a device that has one or more custom YANG data models added to it, back up and remove the configuration data corresponding to the custom YANG data models from the active configuration. For more information see *Managing YANG Packages and Configurations During a Software Upgrade or Downgrade*.

Release Information

Command introduced in Junos OS Release 18.1R1.

request vmhost software in-service-upgrade

IN THIS SECTION

- Syntax | 15551
- Description | 15551
- Options | 15552
- Additional Information | 15553
- Required Privilege Level | 15553
- Sample Output | 15553
- Sample Output | 15554
- Release Information | 15555

Syntax

```
request vmhost software in-service-upgrade package-name
< no-old-master-upgrade>
< reboot>
< verbose>
```

Description

Perform a unified in-service software upgrade (ISSU). A unified ISSU enables you to upgrade from one Junos OS release and host OS release to another with no disruption on the control plane and with

minimal disruption of traffic. For an unified ISSU, graceful Routing Engine switchover (GRES) and nonstop active routing (NSR) must be enabled.

Starting inJunos OS Release 18.2R1, MX10003 routers support unified in-service software upgrade (ISSU) using `request vmhost software in-service-upgrade` command. MX10003 does not support upgrading Junos OS only image using request system software in-service-upgrade command.

NOTE: On MX10003 routers:

- ISSU is not supported on MACsec MIC (JNP-MIC1-MACSEC).
- ISSU is not supported for the interfaces that are configured with 1-Gigabit Ethernet mode. If ISSU upgrade is carried out in 1-Gigabit Ethernet mode, then the behavior is unexpected and traffic loss can be expected.
- ISSU is not supported on timing protocols (like, Precision Time Protocol and Synchronous Ethernet), MACsec protocols, and BBE protocols. If these protocols are already enabled, then it will not work after ISSU is enabled.
- The MAC statistics (retrieved using "show interfaces extensive" on page 20676 command) are reset during ISSU which means that the MAC statistics does not provide the correct statistics after ISSU.

Options

package-name

Location from which the software package or bundle is to be installed. For example:

- `/var/tmp/`*`package-name`*— For a software package or bundle that is being installed from a local directory on the router.
- *`protocol`*`://`*`hostname`*`/`*`pathname`*`/`*`package-name`*—For a software package or bundle that is to be downloaded and installed from a remote location. Replace *`protocol`* with one of the following:
  - `ftp`—File Transfer Protocol (FTP).
  - `http`—Hypertext Transfer Protocol (HTTP).
  - `scp`—Secure Copy Protocol (SCP) (not available for limited editions).

no-old-master-upgrade

(Optional) When the `no-old-master-upgrade` option is included, after the backup Routing Engine is rebooted with the new software package and a switchover occurs to make it the new primary Routing Engine, the former primary (new backup) Routing Engine is not upgraded to the new software. In this case, you must manually upgrade the former

primary (new backup) Routing Engine. If you do not include the `no-old-master-upgrade` option, the system automatically upgrades the former primary Routing Engine.

reboot (Optional) Automatically reboot the former primary (new backup) Routing Engine after the ISSU. If you don not include the `reboot` option in the command, you must manually reboot the former primary (new backup) Routing Engine by using the `request vmhost reboot` command.

verbose (Optional) (MX Series) Use this option to display the daemon related information during the upgrade.

Additional Information

The following conditions apply to unified ISSU:

- Unified ISSU is not supported on every platform. For a list of supported platforms, see Unified ISSU System Requirements.
- Unsupported PICs are restarted during a unified ISSU on certain routing devices.
- During a unified ISSU, any unsupported protocols running on the device causes packet loss.
- During a unified ISSU, you cannot bring any PICs online or take them offline on certain routing devices.

maintenance

Sample Output

request vmhost software in-service-upgrade

```
user@host> request vmhost software in-service-upgrade
/var/tmp/junos-vmhost-install-ptx-x86-64-15.1F5.6.tgz reboot
Chassis ISSU Check Done
[Feb 24 01:12:09]: Starting VMHOST ISSU
[Feb 24 01:12:09]:ISSU: Validating Image
FPC 2 will be offlined (In-Service-Upgrade not supported)
FPC 11 will be offlined (In-Service-Upgrade not supported)
MIC 11/0 will be offlined (In-Service-Upgrade not supported)
Do you want to continue with these actions being taken ? [yes,no] (no) yes
```

```
Junos Validation begin. Procedure will take few minutes.
  ...
  ...
```

Sample Output

request vmhost software in-service-upgrade verbose

```
user@host> request vmhost software in-service-upgrade verbose

- Sample Output | 15557
- Release Information | 15559

Syntax

```
request vmhost  software rollback
<re0 | re1>
<routing-engine>
```

Description

Roll back the Junos OS and the host OS software packages to the previous versions. You can revert to the previous versions of software packages that were loaded at the last successful `request vmhost software add` command.

Options

none—Roll back the software packages of the Routing Engine on the local Virtual Chassis member.

re0 | re1 (Optional) On devices that support dual or redundant Routing Engines, roll back the software packages in Routing Engine in slot 0 (`re0`) or software packages in the Routing Engine in slot 1 (`re1`).

> **NOTE**: The QFX10002-60C and PTX10002-60C devices do not have primary and backup routing engines.

routing-engine (Optional) Specify the Routing Engine on which the software packages needs to be rolled back to the previous set of software packages. The following options are available:

- `backup`—Backup Routing Engine.
- `both`—Both Routing Engines.
- `local`—Routing Engine on the local Virtual Chassis member.
- `master`—Primary Routing Engine.
- `other`—Other Routing Engine.

request vmhost storage

IN THIS SECTION

- Syntax | 15561
- Description | 15561
- Options | 15562
- Required Privilege Level | 15562
- Sample Output | 15562
- Release Information | 15563

Syntax

```
request vmhost storage
request vmhost storage external-ssd initialize slot [0 | 1] public-dir-name [public-disk0 |
public-disk1] force
request vmhost storage external-ssd [add | remove] slot [0 | 1]
```

Description

Initializes an SSD in the specified external SSD slot. It prompts you to confirm and then formats the external SSD so that you can use it for NFX350 device.

Adds or removes an external SSD from its slot. This command also checks the configuration for any VNF path that requires the external disk to be present.

NOTE: External SSDs are not supported on NFX150 and NFX250 devices.

Options

- initialize—Initializes an SSD in the specified external SSD slot 0 or slot 1.
- public-dir-name—Shows the same public-directory path for an SSD even if you move the SSD from one slot to another.
- add—Adds an external SSD to slot 0 or slot 1.
- remove—Removes an external SSD from slot 0 or slot 1.

Required Privilege Level

maintenance

Sample Output

request vmhost storage (NFX150)

```
user@host> request vmhost storage ?
Possible completions:
  <storage-name>       Storage  name
  self-test-long       Long Storage Test
  self-test-messages   Storage Self Test messages
  self-test-short      Long Storage Test
```

request vmhost storage (NFX250 NextGen)

```
user@host> request vmhost storage
Possible completions:
  <storage-name>       Storage  name
  self-test-long       Long Storage Test
  self-test-messages   Storage Self Test messages
  self-test-short      Long Storage Test
```

request vmhost storage (NFX350)

```
user@host> request vmhost storage external-ssd initialize slot 0 public-dir-name public-disk0
force
```

```
Destroy all files on this external SSD and initialize? [yes,no] (no) yes

External SSD in slot 0  initialized, public directory name public-disk0

user@host> request vmhost storage external-ssd add slot 0
External SSD in slot 0 successfully added, accessible at /var/public-disk0
user@host> request vmhost storage external-ssd remove slot 0
Remove SSD paths from device? [yes,no] (no) yes

External SSD in slot 0 successfully removed
user@host> request vmhost storage external-ssd initialize slot 1 public-dir-name public-disk1
force
Destroy all files on this external SSD and initialize? [yes,no] (no) yes

External SSD in slot 1  initialized, public directory name public-disk1
user@host> request vmhost storage external-ssd add slot 1
External SSD in slot 1 successfully added, accessible at /var/public-disk1
user@host> request vmhost storage external-ssd remove slot 1
Remove SSD paths from device? [yes,no] (no) yes

External SSD in slot 1 successfully removed
```

Release Information

Command introduced in Junos OS Release 18.1R1.

request vmhost zeroize

IN THIS SECTION

- Syntax | 15564
- Description | 15564
- Options | 15564
- Required Privilege Level | 15565
- Sample Output | 15565
- Release Information | 15566

Syntax

```
request vmhost zeroize
<re0 | re1>
<routing-engine>
```

Description

Use this command to remove all configuration information on the Routing Engines and reset all key values. If the device has dual Routing Engines, the command is broadcast to both Routing Engines on the device. As a result, both Routing Engines are zeroized. The command removes all data files, including customized configuration and log files from their directories. The command removes all user-created files from the system including all plain-text passwords, secrets, and private keys for SSH, local encryption, local authentication, IPsec, RADIUS, TACACS+, and SNMP.

This command reboots the device and sets it to the factory-default configuration. After the reboot, you cannot access the device through the management Ethernet interface. Log in through the console as the root user and start the Junos OS CLI by typing **cli** at the prompt.

Options

none—Remove all configuration information on all the Routing Engines and reset all key values.

re0 | re1 (Optional) Remove all configuration information on the Routing Engine in slot 0 (`re0`) or the Routing Engine in slot 1 (`re1`).

> **NOTE**: The QFX10002-60C and PTX10002-60C devices do not have primary and backup routing engines.

routing-engine (Optional) Remove all configuration information on the specified Routing Engine. The following options are available:

- `backup`—Backup Routing Engine.
- `both`—Both Routing Engines.
- `local`—Routing Engine on the local Virtual Chassis member.
- `master`—Master Routing Engine.
- `other`—Other Routing Engine.

Required Privilege Level

maintenance

Sample Output

request vmhost zeroize

```
user@host> request vmhost zeroize
VMHost Zeroization :

Erase all data, including configuration and log files?. In case of Dual RE system, both Routing
Engines will be zeroized [yes,no] (no) yes

request vmhost zeroize ztp-option secure

IN THIS SECTION

- Syntax | 15567
- Description | 15567
- Options | 15567

- Required Privilege Level | 15567
- Sample Output | 15568
- Release Information | 15568

Syntax

```
request vmhost zeroize ztp-option secure-(enable | disable)
```

Description

On secure platforms that run secure ZTP (SZTP), you can switch between using SZTP to using zero-touch provisioning (ZTP).

> **NOTE**: On MX304 devices without a backup Routing Engine, when you issue the `request vmhost zeroize ztp-option secure-(enable | disable)` command, you will see the following warning on the console: `Backup RE is not present. Zeroize backup RE when it is inserted.`

Options

enable The CLI checks to see if the device is a secure device. If the device is secure, the process ends. The next time the device boots, the device uses secure ZTP as the provisioning solution. If the device is not a secure device, you will receive an error message that says the device is not secure, and the process ends.

disable The CLI checks to see if the device is a secure device. If the device is a secure device, the next time the device boots, the device uses ZTP as the provisioning solution. If the device is not secure, the process ends.

Required Privilege Level

maintenance

Sample Output

request vmhost zeroize ztp-option-enable

```
user@device> request vmhost zeroize ztp-option secure-enable
```

request vmhost zeroize ztp-option secure-disable

```
user@device> request vmhost zeroize ztp-option secure-disable
```

Release Information

Command introduced in Junos OS Release 23.4R1.

request vpls-switchover

IN THIS SECTION

- Syntax | 15569
- Description | 15569
- Options | 15569
- Required Privilege Level | 15569
- Output Fields | 15569
- Sample Output | 15569
- Release Information | 15569

Syntax

```
request vpls-switchover (instance | logical-system | neighbor | vpls-id)
```

Description

Perform LDP VPLS pseudowire switchover. This provides a way to gracefully recover from pseudowire failures in such a way that Layer 2 circuit and VPLS services can be restarted when an LDP session with the remote PE router goes down.

Options

instance	Name of the VPLS instance.
logical-system	Name of the logical system, or 'all'.
neighbor	IP address of the neighbor.
vpls-id	Layer 2 circuit ID.

Required Privilege Level

view

Output Fields

When you enter this command, you are not provided feedback on the status of your request. You can use the `show vpls connections instance` command to confirm the switchover.

Sample Output

request vpls-switchover vpls-id

```
user@host> request vpls-switchover instance VPLS_16040 vpls-id 16040 neighbor 101.0.0.1
```

Release Information

Command introduced in Junos OS Release 9.2R1.

- Release Information | 15571

Syntax

```
request wlan access-point packet-capture start ap-name interface interface-name duration
duration filename capture-file sizefile-size-max promiscuous filter-mac mac-address
```

Description

Capture the packets for the interfaces on wireless LAN interface Mini-PIM and to check whether the packets are received from Wi-Fi interface and sent to JUNOS. In chassis cluster mode, packet capture command is supported only on active wireless LAN interface.

Options

- `start` *`access-point name`*—Access point name to start the packet capture.
  - `duration`—Specify the capture duration. Range: 10 through 3600 seconds
  - `filename`—Specify the captured filename.

- `filter-mac`—Specify the MAC address of the interface.
- `interface`—Specify the name of the interface.
- `promiscuous`—Enable the promiscuous mode.
- `size`—Specify the maximum file size. Range: 64 through 4096 kilobytes.

- `stop` *`access-point name`*—Stop the packet capture.

Required Privilege Level

view

WHAT'S NEXT

Sample Output

request wlan access-point packet capture

```
user@host> request wlan access-point packet-capture start filename wlan.pcap e09-22-ha-ap
interface Radio1VAP0 duration 10
Starting packet capture

Capture interface:   Radio1VAP0

File             :   wlan.pcap

Duration         :   10 seconds

File size max    :   1024 kilobytes
```

requested-ip-network-match (DHCP Local Server)

IN THIS SECTION

- Syntax | 15572
- Hierarchy Level | 15572
- Description | 15572
- Options | 15573
- Required Privilege Level | 15573
- Release Information | 15573

Syntax

```
requested-ip-network-match subnet-mask;
```

Hierarchy Level

```
[edit system services dhcp-local-server]
[edit system services dhcp-local-server dhcpv6],
[edit logical-systems logical-system-name routing-instances routing-instance-name system
services dhcp-local-server ...],
[edit logical-systems logical-system-name system services dhcp-local-server ...],
[edit routing-instances routing-instance-name system services dhcp-local-server ...]
```

Description

Configure the subnet to which the DHCP local server matches the requested IP address (IPv6 address for DHCPv6 local server). The server accepts and uses the active client's requested address for address assignment only when the requested address and the IP address of the DHCP server interface (or IPv6

address of the DHCPv6 local server) are in the same subnet. The server accepts and uses the passive client's requested address for address assignment only when the requested address and the address of the relay interface are in the same subnet.

Options

subnet-mask

Length of the subnet mask.

- Range:
  - DHCP: 0 through 31
  - DHCPv6: 0 through 127
- Default:
  - DHCP: 8
  - DHCPv6: 16

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.2.

- Release Information | 15575

Syntax

```
required-depth number;
```

Hierarchy Level

```
[edit interfaces interface-name atm-options mpls pop-all-labels],
[edit interfaces interface-name fastether-options mpls pop-all-labels],
[edit interfaces interface-name gigether-options mpls pop-all-labels],
[edit interfaces interface-name sonet-options mpls pop-all-labels]
```

Description

For passive monitoring on ATM, SONET/SDH, Fast Ethernet, and Gigabit Ethernet interfaces only, specify the number of MPLS labels an incoming packet must have for the `pop-all-labels` statement to take effect. For passive monitoring on the MX304 router, MX Series routers with MPCs, and MX series routers with the LC9600 line card, all labels are popped by default and the `required-depth` statement is ignored.

If you include the `required-depth 1` statement, the `pop-all-labels` statement takes effect for incoming packets with one label only. If you include the `required-depth 2` statement, the `pop-all-labels` statement takes effect for incoming packets with two labels only.

Options

number—Number of MPLS labels on incoming IP packets.

- **Range:** 1 through 2 labels.
- **Default:** If you omit this statement, the `pop-all-labels` statement takes effect for incoming packets with one or two labels. The default is equivalent to including the `required-depth [ 1 2 ]` statement.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

reroute-address

IN THIS SECTION

- Syntax | 15576
- Hierarchy Level | 15576
- Description | 15576
- Default | 15576
- Options | 15576
- Required Privilege Level | 15577
- Release Information | 15577

Syntax

```
reroute-address {
    inet address | inet6 address);
}
```

Hierarchy Level

```
[edit forwarding-options evpn-vxlan]
```

Description

Enable fast reroute egress link protection (ELP) on provider edge (PE) devices for access links to multihomed customer edge (CE) devices in an EVPN-VXLAN fabric. This feature helps to minimize load-balanced traffic loss when the link from a PE device to a multihomed CE device goes down.

Remote sources load balance traffic toward a multihomed CE device by distributing portions of the traffic among the multihoming peer PE devices. When you enable this feature on a multihoming PE device, the device creates a backup VXLAN tunnel called an egress link protection (ELP) tunnel to each of its multihoming peer PE devices. If the PE device link to the CE device goes down, the PE device reroutes its portion of the load-balanced traffic to its peer PE devices on the ELP tunnels. The peer PE devices then send the excess load-balanced traffic to the CE device.

The PE device reroutes traffic on the ELP tunnels only until the source device routing table converges. Then the source device stops sending any traffic to the PE device with the bad link, and load balances the traffic only to the other peer PE devices.

To enable this feature, configure this statement and specify an IP address for the ELP tunnel.

Default

Fast reroute egress link protection is not enabled.

Options

inet *address*	Specify the IPv4 address for an ELP reroute tunnel.
inet6 *address*	Specify the IPv6 address for an ELP reroute tunnel.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 21.3R1.

Fast Reroute for Egress Link Protection with EVPN-VXLAN Multihoming

reserve ingress-egress-mcast

IN THIS SECTION

- Syntax | 15577
- Hierarchy Level | 15577
- Description | 15578
- Options | 15578
- Required Privilege Level | 15578
- Release Information | 15578

Syntax

```
reserve ingress-egress-mcast <percentage>;
```

Hierarchy Level

```
[edit system packet-forwarding-options internal-forwarding-bandwidth]
```

Description

You can configure the bandwidth of the recycle interface to enable a percentage of the recycle interface bandwidth for ingress-egress multicast replication.

The following is an example of multicast replication bandwidth calculation:

internal-forwarding-bandwidth = 100Gbps

Reserved ingress-egress-multicast = 40% means

For multicast replication, you can obtain 100Gbps x 40/100 = 40 Gbps per PFE and receiver.

In the above example, 40Gbps is the reserved bandwidth on the recycle port. When you send 100Gbps multicast traffic, then that multicast traffic is forwarded without any drop till 40Gbps, because the remaining 60Gpbs bandwidth was planned for other than multicast applications.

Options

percentage

Recycle interface bandwidth percentage.

- **Range:** 1 through 100 %
- **Default:** 100%

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS EVO Release 21.4R1.

[edit logical-systems logical-system-name protocols pim interface (Protocols PIM)  interface-name],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols pim
interface (Protocols PIM)  interface-name]
```

Description

Change the value of a tracking bit (T-bit) field in the LAN prune delay hello option from the default of 1 to 0, which enables join suppression for a multicast interface. When the network starts receiving multiple identical join messages, join suppression triggers a random timer with a value of 66 through 84 milliseconds (1.1 × periodic through 1.4 × periodic, where periodic is 60 seconds). This creates an interval during which no identical join messages are sent. Eventually, only one of the identical messages is sent. Join suppression is triggered each time identical messages are sent for the same join.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

```

Description

Configure the Juniper Resiliency Interface (JRI) on-box collector to detect exceptions from multiple modules and collect those exceptions in a file or a database. If you want to store exceptions data in a file, you need to configure a filename for the file and the size for the file.

Default

The on-box collector is disabled.

Options

The statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Additional information

To fully configure JRI for forwarding exceptions, you must also:

- Configure inline-monitoring services as you normally would, and configure the Juniper-specific IEs with the `primary-data-record-fields` statement at the `[edit services inline-monitoring templates` *`template-name`*`]` hierarchy level.
- Configure the Observation Cloud identifier with the `observation-cloud-id` statement at the `[edit services inline-monitoring]` hierarchy level.
- Configure exception reporting for a particular inline-monitoring instance with the `exception-reporting` statement at the `[edit chassis fpc` *`name`* `pfe` *`name`*`]` hierarchy level.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 21.2R1 for MX Series routers.

Statement introduced in Junos Evolved OS Release 22.2R1 for PTX Series routers.

resize (Ephemeral Database)

IN THIS SECTION

- Syntax | 15590
- Hierarchy Level | 15591
- Description | 15591
- Default | 15591
- Options | 15591
- Required Privilege Level | 15592
- Release Information | 15592

Syntax

```
resize {
    database-size-diff size MB;
```

```
    database-size-on-disk size MB;
}
```

Hierarchy Level

```
[edit system configuration-database ephemeral instance instance-name]
```

Description

Resize the ephemeral instance's configuration database. The system resizes the database during the commit operation when it meets the criteria in both the `database-size-diff` and `database-size-on-disk` statements. The system displays `Database resize completed` after it successfully resizes the configuration database.

A resize operation involves copying the active configuration objects to a new database and setting the version for each object to the latest version. Resizing the database effectively removes all deleted configuration objects and defragments the database.

Default

If you do not include this statement, the device does not resize the ephemeral database.

Options

none	Enable database resizing and use the default values for the `database-size-diff` and `database-size-on-disk` statements.
`database-size-diff` ***size***	Specify the minimum difference between the database size and the actual usage. • **Default:** 100 MB • **Range:** 1 MB through 1024 MB
`database-size-on-disk` ***size***	Specify the minimum configuration database size on disk. • **Default:** 450 MB • **Range:** 1 MB through 1024 MB

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

        iso-resolution-ribs [ routing-table-names ];
        mpls-import [ policy-names ];
        resolution-family resolution-family;
        resolution-ribs [ routing-table-names ];
```

```
    }
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances routing-instance-name routing-
options],
[edit logical-systems logical-system-name routing-options],
[edit routing-instances routing-instance-name routing-options],
[edit routing-options]
```

Description

Configure the router to perform custom route resolution on protocol next hops of routes in a certain routing table. The protocol next hop is used to determine the forwarding next hop.

For example, you might want to direct **inet.2** route resolution to use topology routing tables **:red.inet.0** and **:blue.inet.0** for protocol next-hop IP address lookups. Or you might want to direct bgp.l3vpn.0 to use the information in inet.0 to resolve routes, thus overriding the default behavior, which is to use inet.3.

You can specify up to two routing tables in the "resolution-ribs" on page 15599 statement. The route resolution scheme first checks the first-listed routing table for the protocol next-hop address. If the address is found, it uses this entry. If it is not found, the resolution scheme checks the second-listed routing table. Hence, only one routing table is used for each protocol next-hop address. For example, if you configure `resolution rib bgp.l3vpn.0 resolution-ribs [inet.0 inet.3]`, inet.0 is checked first and then inet.3 is checked.

> **NOTE**: Customizing route resolution might cause the routing protocol process (rpd) to consume more memory resources than it ordinarily would. When you customize route resolution, we recommend that you check the memory resources by running the `show system processes` and the `show task memory` commands. For more information, see *Routing Protocol Process Overview for EX Series Switches*.

The remaining statements are explained separately. See CLI Explorer.

Options

disable-auto-resolve-on-scheme-changes	(Optional) Service routes are not re-resolved automatically when resolution schemes are created, deleted, or changed. However, you can manually trigger route re-resolution on resolution scheme changes.
inet-import [*policy-names*]	(Optional) Import policy for IPv4 family resolution tree.
inet-resolution-ribs [*routing-table-names*	(Optional) Specify routing tables to use for IPv4 family protocol-next-hop resolution.
inet6-import [*policy-names*]	(Optional) Import policy for IPv6 family resolution tree.
inet6-resolution-ribs [*routing-table-names*]	(Optional) Specify routing tables to use for IPv6 family protocol-next-hop resolution. Enabling the `inet6-resolution-ribs` option causes the static LSP route resolution to happen over the more preferred resolving route (lowest protocol preference) among the longest-matching-prefix routes in both the inet6.0 and inet6.3 routing tables.
iso-import [*policy-names*]	(Optional) Import policy for ISO family resolution tree.
iso-resolution-ribs [*routing-table-names*]	(Optional) Specify routing tables to use for ISO family protocol-next-hop resolution.
resolution-family *resolution-family*	(Optional) Specify a family of resolution tree.
preserve-nexthop-hierarchy	Preserve nexthop hierarchy when installing nexthop to forwarding plane.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

options resolution rib],
[edit logical-systems logical-system-name routing-options resolution rib],
[edit routing-instances routing-instance-name routing-options resolution rib],
[edit routing-options resolution rib]
```

Description

Specify one or more routing tables to use for route resolution.

This statement enables you to override the default routing tables that Junos OS uses for route resolution. For example, suppose that the resolution routing table is **inet.3**, but you want to allow fallback resolution through **inet.0**. One example use case is overriding the **bgp.rtarget.0** (**family route-target**) routing table resolution from using only **inet.3** to using both **inet.3** and **inet.0**.

Options

routing-table-names—Name of one or more routing tables.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

(defaults | route)],
[edit routing-instances routing-instance-name routing-options static (defaults | route)],
[edit routing-options rib routing-table-name static (defaults | route)],
[edit routing-options static (defaults | route)]
```

Description

Statically configure routes to be resolved to a next hop that is not directly connected. The route is resolved through the `inet.0` and `inet.3` routing tables.

NOTE: You cannot configure both `resolve` and `retain` options for a statically configured route because resolved next hops cannot be retained.

Default

Static routes can point only to a directly connected next hop.

TIP: We recommend configuring the `no-resolve` option for individual routes to override default configuration.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

[edit routing-instances routing-instance-name protocols bgp group group-name family inet labeled-
unicast],
[edit routing-instances routing-instance-name protocols bgp group group-name neighbor address
family inet labeled-unicast]
```

Description

Allow labeled routes to be placed in the inet.3 routing table for route resolution. These routes are then resolved for PE router connections where the remote PE is located across another AS. For a PE router to install a route in the VRF, the next hop must resolve to a route stored within the inet.3 table.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

resource-category jtree (Resource Monitor)

IN THIS SECTION

- Syntax | 15606
- Hierarchy Level | 15606
- Description | 15606
- Options | 15606
- Required Privilege Level | 15606
- Release Information | 15607

Syntax

```
resource-category jtree {
resource-type (contiguous-pages | free-dwords | free-pages) {
    low-watermark number;
    high-watermark number;
}
}
```

Hierarchy Level

```
[edit system services resource-monitor]
```

Description

Define the resource category that you want to monitor and analyze for ensuring system stability, especially the health and operating efficiency of I-chip-based line cards and Trio-based FPCs on MX Series routers. The resource category includes detailed CPU utilization, session rate, and session count statistics. You use the resource category statistics to understand the extent to which new attack objects or applications affect performance. The jtree memory on all MX Series router Packet Forwarding Engines has two segments: one segment primarily stores routing tables and related information, and the other segment primarily stores firewall-filter-related information. The Junos OS provides the memory-enhanced statement to reallocate the jtree memory for routes, firewall filters, and Layer 3 VPNs.

Options

jtree Specify the Jtree resource category for which you want to monitor the health (working condition), operating efficiency, traffic-handling capacity, and performance status.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

resource-list (Network Management)

IN THIS SECTION

- Syntax | 15610
- Hierarchy Level | 15610
- Description | 15610
- Options | 15611
- Required Privilege Level | 15611
- Release Information | 15612

Syntax

```
        resource-list resource-list-name resource-names <all-resources> / <ecmp-group> <ecmp-
member> <efp> <egress-l3-interface> <host-ipv4> <host-ipv6> <ifp> <l3-next-hop> <lpm-ipv4> <lpm-
ipv6-128> <lpm-ipv6-64> <mac> <mpls-ingress> <mpls-swap> <tunnel> <vfp> <vport>;
        }
```

Hierarchy Level

```
[edit system packet-forwarding-options hw-resource-monitor]
```

Description

Create a resource list to monitor hardware resource utilization. You can configure multiple resource lists, but the same resource can only be used once and cannot be duplicated on multiple resource lists.

Configure a resource list with multiple resource names, each resource name separated by a space. To add all available resources to the resource list, specify `all-resources` option.

You can map a resource list with a monitor profile (optional) and configure the upper, lower thresholds, and notification type of the monitor profile. You can also configure the polling interval (optional).

No default values.

Options

resource-list-name The name of the resource list.

resource-names The list of resources to monitor.

- `all-resources`—All applicable hardware resources.
- `ecmp-group`—Equal Cost Multi Path (ECMP) group hardware table.
- `ecmp-member`—ECMP member hardware table.
- `efp`—TCAM: Egress Field Processor hardware table.
- `egress-l3-interface`—Egress layer 3 Interface hardware table.
- `host-ipv4`—IPv4 host routes hardware table.
- `host-ipv6`—IPv6 host routes hardware table.
- `ifp`—TCAM: Ingress field processor hardware table.
- `l3-next-hop`—Layer 3 next hop hardware table.
- `lpm-ipv4`—Longest prefix match IPv4 32 bits wide hardware table.
- `lpm-ipv6-128`—Longest prefix match IPv6 128 bits wide hardware table.
- `lpm-ipv6-64`—Longest prefix match IPv6 64 bits wide hardware table.
- `mac`—Layer 2 entry hardware table.
- `mpls-ingress`—Multiprotocol Label Switching (MPLS) ingress hardware table.
- `mpls-swap`—MPLS swap hardware table.
- `tunnel`—IP/Layer 3 tunnel hardware table.
- `vfp`—TCAM: VLAN field processor hardware table.
- `vport`—Virtual port hardware table.

memory],
[edit routing-instances name forwarding-options pfe-sensor npu-memory],
[edit tenants name routing-instances name forwarding-options pfe-sensor npu-memory]
```

Description

Specify a list of resources to monitor and export for Packet Forwarding Engine sensors. If you do not include the `resource-list` statement, information for all active groups in the system is exported. To see a list of groups, use the `show pfe filter hw summary` command.

Export group information to a collector by including the resource path **/junos/system/linecard/npu/memory** in a subscription.

Options

ecmp-group-table	Retrieve equal-cost multipath (ECMP) group table information.
ecmp-member-table	Retrieve ECMP member table information.
efp	Retrieve egress filter information.
egress-l3-interface	Retrieve egress Layer 3 (L3 interface information.
host-ipv4	Retrieve IPv4 host information.
host-ipv6	Retrieve IPv6 host information.
ifp	Retrieve ingress filter information.
l3-next-hop	Retrieve L3 next hop information.
lpm-table-ipv4	Retrieve longest prefix match (LPM) IPv4 table information.
lpm-table-ipv6-128	Retrive LPM IPv6 table information for /128 prefix routes.

lpm-table-ipv6-64	Retrieve LPM IPv6 table information for /64 prefix routes.
mpls-ingress-table	Retrieve MPLS ingress table information
mpls-swap-table	Retrieve MPLS swap table information.
tunnel-table	Retrieve MPLS/LP tunnel table information.
vfp	Retrieve VLAN filter information.
vport	Retrieve Virtual Chassis port (VCP) information.

}
```

Hierarchy Level

```
[edit system services]
```

Description

Enable the resource monitoring capability to provision sufficient headroom (memory space limits that are set for the application or virtual router) for monitoring the health and operating efficiency of DPCs and MPCs. This feature also enables the memory resource monitoring mechanism to avoid the system operations from compromising on the health and traffic-handling stability of the line cards by generating error logs when a specified watermark value for memory regions and threshold value for the jtree memory region are exceeded. A trade-off on the system performance can be detrimental for supporting live traffic and protocols.

The variable *number* in the Syntax section represents a percentage.

You can configure the resource-monitoring capability on MX240, MX480, MX960, MX2010, and MX2020 routers with I-chip-based DPCs and Trio-based FPCs.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 15.1.

`high-cos-queue-threshold` option introduced in Junos OS Release 17.4R1.

resource-watch

IN THIS SECTION

- Syntax | 15622
- Hierarchy Level | 15623
- Description | 15623
- Options | 15623
- Required Privilege Level | 15624
- Release Information | 15625

Syntax

```
resource-watch {
    cpu-statistics;
        junos-statistics;
        orange-zone-enable;
        orange-zone-threshold;
        red-zone-cpu-threshold;
        red-zone-enable;
```

```
        red-zone-jkl-threshold;
        red-zone-snmp-enable;
    resource-watch-enable;
}
```

Hierarchy Level

```
[edit chassis]
```

Description

In SRX chassis cluster mode, split brain caused by redundant failover is triggered due to Routing Engine busy related to CPU overhead causing SRX HA cluster resiliency. To analyze CPU load, Reswatchd is a process running on Linux, Routing Engine3, and Routing Engine2 to collect and monitor the resource usage data. You can generate CPU load statistics report to analyze the system load (resource assignment and Junos kernel usage). You can enable statistics function through CLI to log CPU usage every second and generate a statistics report. This feature is supported on chassis standalone mode to monitor Routing Engine CPU usage and Junos kernel usage and is disabled by default.

Resource availability is classified to three zones:

For RE2, the threshold values are:

- **Green: CPU idle > 20%**
- **Orange: CPU idle <= 15%**
- **Red: CPU idle <= 5% or Junos Kernel load >= 50%**

For RE3, the threshold values are:

- **Green: CPU idle > 10%**
- **Orange: CPU idle <= 10%**
- **Red: CPU idle <= 3% or Junos Kernel load >= 50%**

Options

cpu-statistics Display CPU load statistics report. When enable CPU statistics, reswatchd logs CPU idle values **/var/log/reswatch_CPU_statistics_[1-5]** in .csv format.

- **Range:** `0-604800` seconds.
- Values:
  - `0`—Disable

junos-statistics

Display Junos kernel statistics report. When enable Junos Kernel statistics, reswatchd logs Junos Kernel usage values at **/var/log/reswatch_JK_statistics_[1-5]** in .csv format.

- **Range:** `0-604800` seconds.
- Values:
  - `0`—Disable

orange-zone-enable

Enable orange zone.

orange-zone-threshold

Specify orange zone value (CPU idle %)

- **Default:** `20`
- **Range:** `1-99`

red-zone-cpu-threshold

Specify red zone value (CPU idle %).

- **Default:** `10`
- **Range:** `1-99`

red-zone-enable

Enable red zone.

red-zone-jkl-threshold

Specify red zone value (Junos load %)

- **Default:** `50`
- **Range:** `1-99`

red-zone-snmp-enable

Enable red zone snmp.

resource-watch-enable

Enable resource watch.

- Release Information | **15630**

Syntax

```
response-cache-timeout seconds;
```

Hierarchy Level

```
[edit access radius clients client-name accounting]
```

Description

Configure the timeout for the RADIUS response cache. This timeout indicates how long to store the RADIUS response messages (sent for request messages) in the MX Series router response cache.

Options

seconds Length of timeout interval.

- **Range:** 5 through 20 seconds
- **Default:** 15 seconds

Required Privilege Level

access—To view this statement in the configuration.

access-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 17.1.

    traceoptions {
        flag flag;
```

```
    }
}
```

Hierarchy Level

```
[edit system services]
```

Description

Execute Junos OS commands over HTTP or HTTPS using REST. Optionally, specify JSON output for operational and configuration commands.

Options

routing-instance *routing-instance*

Specify the routing instance through which the remote server is reachable. This can be the non-default management instance mgmt_junos or a user-defined non-default routing instance. If you do not specify a routing instance, REST API requests are sent over the default routing instance.

> **NOTE**: If you want to use the non-default management instance mgmt_junos, you must also define the mgmt_junos routing instance under the `[edit routing-instances]` hierarchy level and configure the `management-instance` statement.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 14.2.

`routing-instance` option introduced in Junos OS Release 20.3R1.

Description

Restart a Junos OS process.

> **CAUTION**: Never restart a software process unless instructed to do so by a customer support engineer. A restart might cause the router or switch to drop calls and interrupt transmission, resulting in possible loss of data.

The `restart` command expands all applications names including applications that are not required for the current platform. Therefore, a user could try to do a restart for an application that is not running for the

current platform. This error message communicates that the restart failed because the application was not running on the system.

Options

none	Same as `gracefully`.
adaptive-services	(Optional) Restart the configuration management process that manages the configuration for stateful firewall, Network Address Translation (NAT), intrusion detection services (IDS), and IP Security (IPsec) services on the Adaptive Services PIC.
all-chassis	(TX Matrix and TX Matrix Plus routers only) (Optional) Restart the software process on all chassis.
all-lcc	(TX Matrix and TX Matrix Plus routers only) (Optional) For a TX Matrix router, restart the software process on all T640 routers connected to the TX Matrix router. For a TX Matrix Plus router, restart the software process on all T1600 routers connected to the TX Matrix Plus router.
all-members	(MX Series routers only) (Optional) Restart the software process for all members of the Virtual Chassis configuration.
all-sfc	(TX Matrix Plus routers only) (Optional) For a TX Matrix Plus router, restart the software processes for the TX Matrix Plus router (or switch-fabric chassis).
ancpd-service	(Optional) Restart the Access Node Control Protocol (ANCP) process, which works with a special Internet Group Management Protocol (IGMP) session to collect outgoing interface mapping events in a scalable manner.
application-identification	(Optional) Restart the process that identifies an application using intrusion detection and prevention (IDP) to allow or deny traffic based on applications running on standard or nonstandard ports.
application-security	(Optional) Restart the application security process.
audit-process	(Optional) Restart the RADIUS accounting process that gathers statistical data that can be used for general network monitoring, analyzing, and tracking usage patterns, for billing a user based on the amount of time or type of services accessed.
auto-configuration	(Optional) Restart the Interface Auto-Configuration process.
autoinstallation	(EX Series switches only) (Optional) Restart the autoinstallation process.

bbe-stats-service	(MX Series routers only) (Optional) Restart bbe-statsd, the BBE statistics collection and management process.
captive-portal-content-delivery	(Optional) Restart the HTTP redirect service by specifying the location to which a subscriber's initial Web browser session is redirected, enabling initial provisioning and service selection for the subscriber.
ce-l2tp-service	(M10, M10i, M7i, and MX Series routers only) (Optional) Restart the Universal Edge Layer 2 Tunneling Protocol (L2TP) process, which establishes L2TP tunnels and Point-to-Point Protocol (PPP) sessions through L2TP tunnels.
chassis-control	(Optional) Restart the chassis management process.
class-of-service	(Optional) Restart the class-of-service (CoS) process, which controls the router's or switch’s CoS configuration.
clksyncd-service	(Optional) Restart the external clock synchronization process, which uses synchronous Ethernet (SyncE).
commitd-service	(Optional) Restart the committed services.
database-replication	(EX Series switches and MX Series routers only) (Optional) Restart the database replication process.
datapath-trace-service	(Optional) Restart the packet path tracing process.
dhcp	(EX Series switches only) (Optional) Restart the software process for a Dynamic Host Configuration Protocol (DHCP) server. A DHCP server allocates network IP addresses and delivers configuration settings to client hosts without user intervention.
dhcp-service	(Optional) Restart the Dynamic Host Configuration Protocol process.
dialer-services	(EX Series switches only) (Optional) Restart the ISDN dial-out process.
diameter-service	(Optional) Restart the diameter process.
disk-monitoring	(Optional) Restart disk monitoring, which checks the health of the hard disk drive on the Routing Engine.
dlsw	(QFX Series only) (Optional) Restart the data link switching (DLSw) service.
dot1x-protocol	(EX Series switches only) (Optional) Restart the port-based network access control process.

dynamic-flow-capture	(Optional) Restart the dynamic flow capture (DFC) process, which controls DFC configurations on Monitoring Services III PICs.
ecc-error-logging	(Optional) Restart the error checking and correction (ECC) process, which logs ECC parity errors in memory on the Routing Engine.
ethernet-connectivity-fault-management	(Optional) Restart the process that provides IEEE 802.1ag Operation, Administration, and Management (OAM) connectivity fault management (CFM) database information for CFM maintenance association end points (MEPs) in a CFM session.
ethernet-link-fault-management	(EX Series switches and MX Series routers only) (Optional) Restart the process that provides the OAM link fault management (LFM) information for Ethernet interfaces.
ethernet-switching	(EX Series switches only) (Optional) Restart the Ethernet switching process.
event-processing	(Optional) Restart the event process (eventd).
extensible-subscriber-services	(Optional) Restart the extensible subscriber services process.
fibre-channel	(QFX Series only) (Optional) Restart the Fibre Channel process.
fipsd	(Optional) Restart the fipsd services.
firewall	(Optional) Restart the firewall management process, which manages the firewall configuration and enables accepting or rejecting packets that are transiting an interface on a router or switch.
general-authentication-service	(EX Series switches and MX Series routers only) (Optional) Restart the general authentication process.
gprs-process	(Optional) Restart the General Packet Radio Service (GPRS) process.
gracefully	(Optional) Restart the software process.
iccp-service	(Optional) Restart the Inter-Chassis Communication Protocol (ICCP) process.
idp-policy	(Optional) Restart the intrusion detection and prevention (IDP) protocol process.
immediately	(Optional) Immediately restart the software process.
interface-control	(Optional) Restart the interface process, which controls the router's or switch’s physical interface devices and logical interfaces.

ipmi	(Optional) Restart the intelligent platform management interface process.
ipsec-key-management	(Optional) Restart the IPsec key management process.
isdn-signaling	(QFX Series only) (Optional) Restart the ISDN signaling process, which initiates ISDN connections.
jflow-service	(Optional) Restart jflow service process.
jnu-management	(Optional) Restart jnu management process.
jnx-wmicd-service	(Optional) Restart jnx wmicd service process.
jsrp-service	(Optional) Restart the Juniper Services Redundancy Protocol (jsrdp) process, which controls chassis clustering.
kernel-health-monitoring	(Optional) Restart the Routing Engine kernel health monitoring process, which enables health parameter data to be sent from kernel components to data collection applications. When you change the polling interval through `sysctl kern.jkhmd_polling_time_secs`, you must restart the kernel health monitoring process for the new polling interval to take effect.
kernel-replication	(Optional) Restart the kernel replication process, which replicates the state of the backup Routing Engine when graceful Routing Engine switchover (GRES) is configured.
l2-learning	(Optional) Restart the Layer 2 address flooding and learning process.
l2cpd-service	(Optional) Restart the Layer 2 Control Protocol process, which enables features such as Layer 2 protocol tunneling and nonstop bridging.
l2tp-service	(M10, M10i, M7i, and MX Series routers only) (Optional) Restart the Layer 2 Tunneling Protocol (L2TP) process, which sets up client services for establishing Point-to-Point Protocol (PPP) tunnels across a network and negotiating Multilink PPP if it is implemented.
l2tp-universal-edge	(MX Series routers only) (Optional) Restart the L2TP process, which establishes L2TP tunnels and PPP sessions through L2TP tunnels.
lacp	(Optional) Restart the Link Aggregation Control Protocol (LACP) process. LACP provides a standardized means for exchanging information between partner systems on a link to allow their link aggregation control instances to reach agreement on the identity of the LAG to which the link belongs, and then to

move the link to that LAG, and to enable the transmission and reception processes for the link to function in an orderly manner.

lcc *number*

(TX Matrix and TX Matrix Plus routers only) (Optional) For a TX Matrix router, restart the software process for a specific T640 router that is connected to the TX Matrix router. For a TX Matrix Plus router, restart the software process for a specific router that is connected to the TX Matrix Plus router.

Replace *number* with the following values depending on the LCC configuration:

- 0 through 3, when T640 routers are connected to a TX Matrix router in a routing matrix.
- 0 through 3, when T1600 routers are connected to a TX Matrix Plus router in a routing matrix.
- 0 through 7, when T1600 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.
- 0, 2, 4, or 6, when T4000 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.

license-service

(EX Series switches only) (Optional) Restart the feature license management process.

link-management

(TX Matrix and TX Matrix Plus routers and EX Series switches only) (Optional) Restart the Link Management Protocol (LMP) process, which establishes and maintains LMP control channels.

lldpd-service

(EX Series switches only) (Optional) Restart the Link Layer Discovery Protocol (LLDP) process.

local

(MX Series routers only) (Optional) Restart the software process for the local Virtual Chassis member.

local-policy-decision-function

(Optional) Restart the process for the Local Policy Decision Function, which regulates collection of statistics related to applications and application groups and tracking of information about dynamic subscribers and static interfaces.

logical-system-service

(Optional) Restart the logical system service process.

mac-validation

(Optional) Restart the Media Access Control (MAC) validation process, which configures MAC address validation for subscriber interfaces created on demux interfaces in dynamic profiles on MX Series routers.

member ***member-id***	(MX Series routers only) (Optional) Restart the software process for a specific member of the Virtual Chassis configuration. Replace *member-id* with a value of `0` or `1`.
mib-process	(Optional) Restart the Management Information Base (MIB) version II process, which provides the router's MIB II agent.
mobile-ip	(Optional) Restart the Mobile IP process, which configures Junos OS Mobile IP features.
mountd-service	(EX Series switches and MX Series routers only) (Optional) Restart the service for NFS mount requests.
mpls-traceroute	(Optional) Restart the MPLS Periodic Traceroute process.
mspd	(Optional) Restart the Multiservice process.
multicast-snooping	(EX Series switches and MX Series routers only) (Optional) Restart the multicast snooping process, which makes Layer 2 devices, such as VLAN switches, aware of Layer 3 information, such as the media access control (MAC) addresses of members of a multicast group.
named-service	(Optional) Restart the DNS Server process, which is used by a router or a switch to resolve hostnames into addresses.
network-access-service	(QFX Series only) (Optional) Restart the network access process, which provides the router's Challenge Handshake Authentication Protocol (CHAP) authentication service.
network-security	(Optional) Restart the network security process.
network-security-trace	(Optional) Restart the network security trace process.
nfsd-service	(Optional) Restart the Remote NFS Server process, which provides remote file access for applications that need NFS-based transport.
ntpd-service	(Optional) Restart the Network Time Protocol (NTP) process.
packet-triggered-subscribers	(Optional) Restart the packet-triggered subscribers and policy control (PTSP) process, which allows the application of policies to dynamic subscribers that are controlled by a subscriber termination device.
peer-selection-service	(Optional) Restart the Peer Selection Service process.

pgcp-service	(Optional) Restart the pgcpd service process running on the Routing Engine. This option does not restart pgcpd processes running on mobile station PICs. To restart pgcpd processes running on mobile station PICs, use the `services pgcp gateway` option.
pgm	(Optional) Restart the process that implements the Pragmatic General Multicast (PGM) protocol for assisting in the reliable delivery of multicast packets.
pic-services-logging	(Optional) Restart the logging process for some PICs. With this process, also known as fsad (the file system access daemon), PICs send special logging information to the Routing Engine for archiving on the hard disk.
pki-service	(Optional) Restart the PKI Service process.
ppp	(Optional) Restart the Point-to-Point Protocol (PPP) process, which is the encapsulation protocol process for transporting IP traffic across point-to-point links.
ppp-service	(Optional) Restart the Universal edge PPP process, which is the encapsulation protocol process for transporting IP traffic across universal edge routers.
pppoe	(Optional) Restart the Point-to-Point Protocol over Ethernet (PPPoE) process, which combines PPP that typically runs over broadband connections with the Ethernet link-layer protocol that allows users to connect to a network of hosts over a bridge or access concentrator.
profilerd	(Optional) Restart the profiler process.
protected-system-domain-service	(Optional) Restart the Protected System Domain (PSD) process.
redundancy-interface-process	(Optional) Restart the ASP redundancy process.
remote-operations	(Optional) Restart the remote operations process, which provides the ping and traceroute MIBs.
rest-api	(Optional) Restart the rest api process.
root-system-domain-service	(Optional) Restart the Root System Domain (RSD) service.
routing	(ACX Series routers, QFX Series, EX Series switches, and MX Series routers only) (Optional) Restart the routing protocol process.
routing <logical-system *logical-system-name*>	(Optional) Restart the routing protocol process, which controls the routing protocols that run on the router or switch and maintains the routing tables.

	Optionally, restart the routing protocol process for the specified logical system only.
sampling	(Optional) Restart the sampling process, which performs packet sampling based on particular input interfaces and various fields in the packet header.
sampling-route-record	(Optional) Restart the sampling route record process.
sbc-configuration-process	(Optional) Restart the session border controller (SBC) process of the border signaling gateway (BSG).
scc	(TX Matrix routers only) (Optional) Restart the software process on the TX Matrix router (or switch-card chassis).
scc-chassisd	(Optional) Restart the scc chassisd process.
sdk-service	(Optional) Restart the SDK Service process, which runs on the Routing Engine and is responsible for communications between the SDK application and Junos OS. Although the SDK Service process is present on the router, it is turned off by default.
secure-neighbor-discovery	(QFX Series, EX Series switches, and MX Series routers only) (Optional) Restart the secure Neighbor Discovery Protocol (NDP) process, which provides support for protecting NDP messages.
security-intelligence	(Optional) Restart security intelligence process.
security-log	(Optional) Restart the security log process.
sfc *number*	(TX Matrix Plus routers only) (Optional) Restart the software process on the TX Matrix Plus router (or switch-fabric chassis). Replace *number* with `0`.
service-deployment	(Optional) Restart the service deployment process, which enables Junos OS to work with the Session and Resource Control (SRC) software.
services	(Optional) Restart a service.
services pgcp gateway *gateway-name*	(Optional) Restart the pgcpd process for a specific border gateway function (BGF) running on an MS-PIC. This option does not restart the pgcpd process running on the Routing Engine. To restart the pgcpd process on the Routing Engine, use the `pgcp-service` option.
sflow-service	(EX Series switches only) (Optional) Restart the flow sampling (sFlow technology) process.

simple-mail-client-service	(Optional) Restart the simple mail client service process.
snmp	(Optional) Restart the SNMP process, which enables the monitoring of network devices from a central location and provides the router's or switch's SNMP master agent.
soft	(Optional) Reread and reactivate the configuration without completely restarting the software processes. For example, BGP peers stay up and the routing table stays constant. Omitting this option results in a graceful restart of the software process.
static-routed	(Optional) Restart the static routed process.
static-subscribers	(Optional) Restart the static subscribers process, which associates subscribers with statically configured interfaces and provides dynamic service activation and activation for these subscribers.
statistics-service	(Optional) Restart the process that manages the Packet Forwarding Engine statistics.
subscriber-management	(Optional) Restart the Subscriber Management process.
subscriber-management-helper	(Optional) Restart the Subscriber Management Helper process.
system-log-vital	(Optional) Restart system log vital process.
tunnel-oamd	(Optional) Restart the Tunnel OAM process, which enables the Operations, Administration, and Maintenance of Layer 2 tunneled networks. Layer 2 protocol tunneling (L2PT) allows service providers to send Layer 2 protocol data units (PDUs) across the provider's cloud and deliver them to Juniper Networks EX Series Ethernet Switches that are not part of the local broadcast domain.
uac-service	(Optional) Restart the Unified Access Control (UAC) process.
usb-control	(MX Series routers) (Optional) Restart the USB control process.
user-ad-authentication	(Optional) Restart User ad Authentication process
vrrp	(ACX Series routers, EX Series switches, and MX Series routers only) (Optional) Restart the Virtual Router Redundancy Protocol (VRRP) process, which enables hosts on a LAN to make use of redundant routing platforms on that LAN without requiring more than the static configuration of a single default route on the hosts.

web-management (QFX Series, EX Series switches, and MX Series routers only) (Optional) Restart the Web management process.

Required Privilege Level

reset

Output Fields

When you enter this command, you are provided feedback on the status of your request.

Sample Output

restart interfaces

```
user@host> restart interfaces
interfaces process terminated
interfaces process restarted
```

restart interface-control gracefully

```
user@host> restart interface-control gracefully
Interface control process started, pid 41129
```

restart interface-control (Junos OS Evolved)

```
user@host> restart interface-control
interface-control restart requested
Restarted aggd on re0
Restarted ifmand on re0
```

Release Information

Command introduced before Junos OS Release 7.4.

Options added:

- `dynamic-flow-capture` in Junos OS Release 7.4.
- `dlsw` in Junos OS Release 7.5.
- `event-processing` in Junos OS Release 7.5.
- `ppp` in Junos OS Release 7.5.
- `l2ald` in Junos OS Release 8.0.
- `link-management` in Junos Release 8.0.
- `pgcp-service` in Junos OS Release 8.4.
- `sbc-configuration-process` in Junos OS Release 9.5.
- `services pgcp gateway` in Junos OS Release 9.6.
- `sfc` and `all-sfc` for the TX Matrix Router in Junos OS Release 9.6.
- Command introduced before Junos OS Release 9.2 on SRX Series Firewalls.
- `bbe-stats-service` in Junos OS Release 18.4R1 on MX Series routers.
- `kernel-health-monitoring` in Junos OS Release 19.1R1.
- Introduced in Junos OS Evolved Release 19.1R1.

Overview of Operational Mode Commands

restart chassis-control

IN THIS SECTION

- Syntax | **15649**
- Syntax (TX Matrix Routers) | **15649**
- Syntax (TX Matrix Plus Routers) | **15649**
- Description | **15649**

- Options | 15650
- Required Privilege Level | 15650
- Output Fields | 15650
- Sample Output | 15651
- Release Information | 15651

Syntax

```
restart chassis-control
<gracefully | immediately | soft>
```

Syntax (TX Matrix Routers)

```
restart chassis-control
<all-chassis | all-lcc | lcc number | scc>
<gracefully | immediately | soft>
```

Syntax (TX Matrix Plus Routers)

```
restart chassis-control
<all-chassis | all-lcc | all-sfc | lcc number | sfc number>
<gracefully | immediately | soft>
```

Description

Restart the chassis management process.

NOTE: When GRES is configured and the `restart chassis-control` command is executed on a TX Matrix Plus router with 3D SIBs, we cannot ascertain which Routing Engine becomes a primary. This is due to the chassisd restart. The chassis process or chassisd is responsible for maintaining and retaining primary role and when it is restarted, the new

chassisd is processed based on the router load. This results in one of the Routing Engines being made primary.

Options

lcc *number* (Routing matrix only) (Optional) Restart the software process for a specific routing node that is connected to a PTX Matrix platform. Replace ***number*** with a value from **0** through **3**.

sfc *number* (PTX routers only) (Optional) Restart the software process on the PTX series router (or switch-fabric chassis). Replace ***number*** with **0**.

gracefully (Optional) Restart the software process.

immediately (Optional) Immediately restart the software process.

> **NOTE**: For PTX Series routers, when the `restart chassis-control` command is executed with the `immediately` option set, the PFE's state will be reset to enabled regardless of whether or not the PFE's state is set to disabled when the action occurs.

soft (Optional) Reread and reactivate the configuration without completely restarting the software processes. For example, Border Gateway Protocol (BGP) peers stay up and the routing table stays constant. Omitting this option results in a graceful restart of the software process.

Required Privilege Level

reset

Output Fields

When you enter this command, you are provided feedback on the status of your request.

Sample Output

restart chassis-control gracefully

```
user@host> restart chassis-control gracefully
Chassis control process started, pid 1631
```

restart chassis-control soft

```
user@host> restart chassis-control soft
Chassis control process started, pid 1653
```

Release Information

Command introduced before JUNOS Release 7.4.

Command added in Junos Evolved Release 21.4R1.

RELATED DOCUMENTATION

restart | 15633

restart-duration (Protocols)

IN THIS SECTION

- Syntax | 15652
- Hierarchy Level | 15652
- Description | 15652
- Options | 15652
- Required Privilege Level | 15653
- Release Information | 15653

Syntax

```
restart-duration seconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols (isis | ospf | ospf3 | pim) graceful-restart],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols
(ospf | ospf3 | pim) graceful-restart],
[edit protocols (esis | isis | ospf | ospf3 | pim) graceful-restart],
[edit routing-instances routing-instance-name protocols (ospf | ospf3 | pim) graceful-restart],
[edit routing-options graceful-restart]
```

Description

Configure the grace period for graceful restart globally.

Additionally, you can individually configure the duration of the graceful restart period for the End System-to-Intermediate System (ES-IS), Intermediate System-to-Intermediate System (IS-IS), Open Shortest Path First (OSPF), and OSPFv3 protocols and for Protocol Independent Multicast (PIM) sparse mode.

Options

seconds—Time for the graceful restart period.

Range:

- The range of values varies according to whether the graceful restart period is being set globally or for a particular protocol:
  - `[edit routing-options graceful-restart]` (global setting)—120 through 900
  - ES-IS—30 through 300
  - IS-IS—30 through 300
  - OSPF/OSPFv3—1 through 3600
  - PIM—30 through 300

Default:

- The default value varies according to whether the graceful restart period is being set globally or for a particular protocol:
  - `[edit routing-options graceful-restart]` (global setting)—300
  - ES-IS—180
  - IS-IS—210
  - OSPF/OSPFv3—180
  - PIM—60

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

restart (JDM)

IN THIS SECTION

Syntax | 15658

- Description | 15658
- Options | 15658
- Required Privilege Level | 15659
- Output Fields | 15659
- Sample Output | 15659
- Release Information | 15659

Syntax

```
restart (gracefully | immediately | soft)
<jdmd>
<jdmmon>
<jinventoryd>
<jlinkmon>
```

Description

Restart daemons belonging to Juniper Device Manager (JDM).

CAUTION: Never restart a software process unless instructed to do so by a customer support engineer.

NOTE: Starting in Junos OS Release 19.2R1, JDM does not support the `jinventoryd` option in the `restart` command.

Options

gracefully (Optional) Restart a specified module or component by sending the equivalent of a UNIX SIGTERM signal.

immediately (Optional) Immediately restart a module or component by sending the equivalent of a UNIX SIGKILL signal.

soft (Optional) Reread and reactivate the configuration without completely restarting a module or component. This option is the equivalent of a UNIX SIGHUP signal.

jdmd Restart the JDM service process.

jdmmon Restart the JDM link monitoring daemon.

jinventoryd Restart the JDM inventory management daemon.

jlinkmon Restart the JDM link monitor daemon, which runs on the Linux host.

> **NOTE**: The options `gracefully`, `immediately`, and `soft` are not available for restarting the Juniper link monitor daemon.

Required Privilege Level

Output Fields

When you enter this command, you are provided feedback on the status of your request.

Sample Output

restart jdmd gracefully

```
user@jdm> restart jdmd gracefully
Juniper Device Manager service process started, pid 12058
```

Release Information

Command introduced in Junos OS Release 17.4R1.

restart (Junos OS Evolved)

IN THIS SECTION

- Syntax | 15660
- Description | 15660
- Options | 15661
- Required Privilege Level | 15661
- Output Fields | 15661
- Sample Output | 15661
- Release Information | 15662

Syntax

```
restart application-name
<gracefully | immediately | soft>
```

Description

Restart a Junos OS Evolved process.

> **CAUTION**: Never restart a software process unless instructed to do so by a customer support engineer. A restart might cause the router or switch to drop calls and interrupt transmission, resulting in possible loss of data.

For Junos OS Evolved, the `restart` command also triggers a restart of the dependent applications (apps). To inform you which dependent apps restarted, the following message appears in the log whenever you use the `restart` command:

`App restarting <app name>. Related apps that may be impacted - <related-app name>` . For example: `Jan 14 11:42:08 RE0 sysman[5100]: SYSTEM_APP_RESTARTING_WITH_RELAPPS_EVENT: App restarting re0-ifmand. Related apps that may be impacted - aggd`

Starting in Junos OS Evolved Release 20.1R1, if you specify the `restart` *`app-name`* command and the application is not supposed to run on the platform, the error message is as follows:

```
user@device> restart fabspoked-pfe
Restart failed for fabspoked-pfe on node re0. Application is not running.
```

The `restart` command expands all application names, including applications not required for the current platform. Therefore, you could try to restart an application that is not running for the current platform. This error message communicates that the restart failed because the application was not running on the system.

Options

application-name	Specify the name of the application you want to restart. Use the `show system applications` operational mode command for information about what applications are running.
none	Same as `gracefully`.
`gracefully`	(Optional) Gracefully restart the software process.
`immediately`	(Optional) Immediately restart the software process.
`soft`	(Optional) Re-read and reactivate the configuration without completely restarting the software processes. For example, BGP peers stay up and the routing table stays constant. Omitting this option results in a graceful restart of the software process.

Required Privilege Level

reset

Output Fields

When you enter this command, the system provides feedback on the status of your request.

Sample Output

restart interface-control (Junos OS Evolved)

```
user@host> restart interface-control
interface-control restart requested
```

```
Restarted aggd on re0
Restarted ifmand on re0
```

Release Information

Introduced in Junos OS Evolved Release 19.1R1.

restart-path

IN THIS SECTION

- Syntax | 15662
- Hierarchy Level | 15662
- Description | 15662
- Options | 15663
- Required Privilege Level | 15663
- Release Information | 15663

Syntax

```
restart-path (all | create | echo);
```

Hierarchy Level

```
[edit security gtp profile profile-name]
```

Description

Use the restart-path function to restart a GTP path. By default, the restart path is disabled and then related function does not work. Tunnels are not deleted when restart counter changes.

From Junos OS Release 20.4R1 onwards, the [`edit security gprs gtp profile` *`profile-name`*] hierarchy level is replaced by [`edit security gtp profile` *`profile-name`*].

Options

- **all**—Restart GTP paths by detecting the changed restart number obtained from the Recovery information element (IE) in all GTP messages.
- **create**—Restart GTP paths by detecting the changed restart number obtained from the Recovery IE in create-session messages.
- **echo**—Restart GTP paths by detecting the changed restart number obtained from the Recovery IE in echo messages.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.4. Support.

RELATED DOCUMENTATION

Example: Restarting a GTPv2 Path

restart-time (BGP Graceful Restart)

IN THIS SECTION

- Syntax | 15664
- Hierarchy Level | 15664
- Description | 15664

- Options | 15664
- Required Privilege Level | 15665
- Release Information | 15665

Syntax

```
restart-time seconds;
```

Hierarchy Level

```
[edit protocols (bgp | rip | ripng) graceful-restart],
[edit logical-systems logical-system-name protocols (bgp | rip | ripng) graceful-restart (Enabling Globally)],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols bgp graceful-restart],
[edit routing-instances routing-instance-name protocols bgp graceful-restart]
```

Description

Configure the duration of the BGP, RIP, or next-generation RIP (RIPng) graceful restart period.

Options

seconds—Length of time for the graceful restart period.

- **Range:** Varies by protocol
  - BGP— 1 through 1800 seconds
  - RIP — 1 through 600 seconds
- **Default:** Varies by protocol:
  - BGP—120 seconds
  - RIP and RIPng—60 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.3.

stale-routes-time | 28478

restart-time (Fabric Control)

IN THIS SECTION

- Syntax | 15665
- Hierarchy Level | 15666
- Description | 15666
- Options | 15666
- Required Privilege Level | 15666
- Release Information | 15666

Syntax

```
restart-time seconds;
```

Hierarchy Level

```
[edit fabric protocols fabric-control graceful-restart]
```

Description

Configure the duration of the graceful restart period for the fabric control Routing Engine.

The graceful restart resynchronization process takes longer when the QFabric system contains node groups that have a large number of VLANs. The graceful-restart duration should, therefore, be set higher when the QFabric system contains at least one node group with a large number of VLANs.

Configure a restart time of 600 seconds if the number of VLAN members (vmembers) exceeds 32k.

> **CAUTION**: Configuring the restart time restarts the session between the fabric control Routing Engine and the Node groups. Traffic is dropped as a result of this restart. Normal QFabric system operations should resume once the session has restarted without any further user actions.

Options

seconds Duration of the graceful restart period.

- **Default:** 300 seconds
- **Range:** 300 to 900 seconds

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 13.2X52-D10.

family (l2vpn | route-target | inet) (labeled-unicast | flow) graceful-restart long-lived],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols bgp
```

```
group group-name family (l2vpn | route-target | inet) (labeled-unicast | flow) graceful-restart
long-lived],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols bgp
group group-name neighbor address family (l2vpn | route-target | inet) (labeled-unicast | flow)
graceful-restart long-lived],
[edit routing-instances routing-instance-name protocols bgp family (l2vpn | route-target | inet)
(labeled-unicast | flow) graceful-restart long-lived],
[edit routing-instances routing-instance-name protocols bgp group group-name family (l2vpn |
route-target | inet) (labeled-unicast | flow) graceful-restart long-lived],
[edit routing-instances routing-instance-name protocols bgp group group-name neighbor address
family (l2vpn | route-target | inet) (labeled-unicast | flow) graceful-restart long-lived],
[edit protocols bgp family (l2vpn | route-target | inet) (labeled-unicast | flow) graceful-
restart long-lived],
[edit protocols bgp group group-name family (l2vpn | route-target | inet) (labeled-unicast |
flow) graceful-restart long-lived],
[edit protocols bgp group group-name neighbor address family (l2vpn | route-target | inet)
(labeled-unicast | flow) graceful-restart long-lived]
```

NOTE: Each routing table is identified by the protocol family or address family indicator (AFI) and a subsequent address family identifier (SAFI). The AFI parameter can be one of the `(l2vpn | inet | route-target)` protocols and the SAFI parameter can be either of the `(flow | labeled-unicast)` protocols for inet family and one of the `(auto-discovery-mspw | auto-discovery-only | signaling)` protcols for L2VPN family..

Configuring LLGR does not require that BGP graceful restart also be configured. The long-lived-graceful-restart section is visible only for families l2vpn, inet labeled-unicast, inet flow and route-target. It is prohibited for inet-mvpn, inet6-mvpn and inet-mdt. It is hidden for other families.

Description

Configure the long-lived graceful restart mechanism for a BGP restarter router to preserve BGP routing details for a longer period from a failed BGP peer. You can also configure the BGP long-lived graceful restarter mode negotiation mechanism for a particular address family instead of configuring this capability for all address families in a system, logical system, or routing instance.

The stanzas in the per-family graceful-restart long-lived restarter configuration section enables LLGR restarter mode negotiation for BGP globally, or for a group or neighbor. The values are inherited by groups from the global configuration, and by neighbors from the group configuration. The disable attribute is used to override configuration inherited from a higher level. It does not disable LLGR receiver mode; you must disable LLGR receiver mode explicitly for all families as necessary. A hidden `enable` attribute can be used to override an inherited disable attribute. Configuring graceful-restart long-lived

restarter at the neighbor level (when it is not configured at the containing group level or globally) causes an internal group to be split. When LLGR restarter is enabled or disabled for a family or the stale- time is changed, the session is reset so that the new capability can be sent to the neighbor.

Options

The remaining statements are explained separately. See CLI Explorer.

(defaults | route)],
[edit routing-instances routing-instance-name routing-options static (defaults | route)],
[edit routing-options rib routing-table-name static (defaults | route)],
[edit routing-options static (defaults | route)]
```

Description

Configure statically configured routes to be deleted from or retained in the forwarding table when the routing protocol process shuts down normally.

> **NOTE**: You cannot configure both `retain` and `resolve` options for a statically configured route because resolved next hops cannot be retained.

Default

Statically configured routes are deleted from the forwarding table when the routing protocol process shuts down normally.

The retention policy applied to defaults and route is as follows:

- defaults— The default route retention policy. By default, the default route retention policy is no-retain for the configured scope using the `defaults` configuration statement. This default retention policy is overridden on a per route basis using the routes option.
- route—The retention policy for this route. The default retention policy for a route is the policy of its routing table.

Options

no-retain Delete statically configured routes from the forwarding table when the routing protocol process shuts down normally. To explicitly specify that routes be deleted from the forwarding table, include the `no-retain` statement. Include this statement when configuring an individual route in the `route` portion of the `static` statement to override a `retain` option specified in the `defaults` portion of the statement.

retain Have a static route remain in the forwarding table when the routing protocol process shuts down normally. Doing this greatly reduces the time required to restart a system that has a large number of routes in its routing table.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

```

Description

Specify the number of redundant Ethernet (`reth`) interfaces allowed in the chassis cluster. You need to specify the total number of interfaces in the chassis cluster before redundant Ethernet interfaces are created. For example, the `set chassis cluster reth-count 2` allow you to create two reth interfaces (example: reth0 and reth1)

Note that the number of `reth` interfaces configured determines the number of redundancy groups that can be configured and each SRX Series Firewall has a maximum number of reths that it can support.

Options

number —Number of redundant Ethernet interfaces allowed.

- **Range:** 1 through 128
- **Default:** 0

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.0.

RELATED DOCUMENTATION

retransmission-attempt (DHCP Client)

IN THIS SECTION

- Syntax | 15677
- Hierarchy Level | 15677
- Description | 15677
- Options | 15677
- Required Privilege Level | 15678
- Release Information | 15678

Syntax

```
retransmission-attempts number;
```

Hierarchy Level

```
[edit interfaces interface-name unit logical-unit-number family family dhcp-client]
```

Description

Specify the number of times the device attempts to retransmit a Dynamic Host Control Protocol (DHCP) packet fallback.

Options

number Number of retransmit attempts.

Range:

- - For IPv4 — 0 through 50000 from Junos OS Release 17.3R1 onwards and 0 through 6 on Junos OS earlier releases.
  - For IPv6 — 0 through 9.

- **Default:** 4

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.1X44-D10.

Starting with Junos OS Release 17.3R1, on all SRX Series Firewalls and vSRX Virtual Firewall instances, the CLI option `dhcp-clinet` at `[edit interfaces interface-name unit logical-unit-number family inet]` hierarchy is changed to `dhcp` to keep consistent with other Junos platforms. There is no change in the functionality with the changed CLI option `dhcp`.

retransmission-attempt (DHCPv6 Client)

IN THIS SECTION

- Syntax | 15679
- Hierarchy Level | 15679
- Description | 15679
- Options | 15679
- Required Privilege Level | 15679
- Release Information | 15679

Syntax

```
retransmission-attempt number;
```

Hierarchy Level

```
[edit interfaces interface-name unit logical-unit-number family family dhcpv6-client]
[edit logical-systems logical-system-name interfaces interface-name unit logical-unit-number
family inet6 dhcpv6-client]
[edit tenants tenant-name interfaces interface-name unit logical-unit-number family inet6 dhcpv6-
client]
```

Description

Specify the number of times the device retransmits a DHCPv6 client packet if a DHCPv6 server fails to respond. After the specified number of attempts, no further attempts at reaching a server are made.

Options

number Number of retransmit attempts.

- **Range:** 0 through 50000 (from Junos OS Release 20.3R1 onwards)
- **Range:** 0 through 9

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.1X45-D10.

The `logical-systems` and `tenants` options are introduced in Junos OS Release 18.4R1.

retransmission-count-established (L2TP)

IN THIS SECTION

- Syntax | 15680
- Hierarchy Level | 15680
- Description | 15680
- Options | 15680
- Required Privilege Level | 15681
- Release Information | 15681

Syntax

```
retransmission-count-established count;
```

Hierarchy Level

```
[edit services l2tp tunnel]
```

Description

Set the maximum number of times control messages are retransmitted for established tunnels.

BEST PRACTICE: Before you downgrade to a Junos OS Release that does not support this statement, unconfigure the statement by issuing `no services l2tp tunnel retransmission-count-established`.

Options

count—Number of retransmissions.

- **Range:** 2 through 30

- **Default:** 7

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

retransmission-interval (DHCP Client)

IN THIS SECTION

Syntax | 15686

- Hierarchy Level | 15686
- Description | 15686
- Options | 15686
- Required Privilege Level | 15687
- Release Information | 15687

Syntax

```
retransmission-interval seconds;
```

Hierarchy Level

```
[edit interfaces interface-name unit logical-unit-number family family dhcp-client]
```

Description

Specify the initial retransmission interval. Successive retransmission intervals are doubled as per RFC2131.

> **NOTE**: Though the SRX Series Firewalls implement the exponential backoff, as described in RFC 2131, the retransmit attempt does not stop when the retransmission interval reaches 64 seconds. The packet is transmitted till the retransmission attempt is reached. For example, if you configure the `retransmission-attempt` to 5 and the `retransmission-interval` to 20, the sequence of retransmission-interval is 20, 40, 80, 160, 320.

Options

seconds Number of seconds before initial retransmission.

Range: The range is 4 through 64. The default is 4 seconds.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

retry-count (Chassis Cluster)

IN THIS SECTION

- Syntax | 15700
- Hierarchy Level | 15700
- Description | 15700
- Options | 15701
- Required Privilege Level | 15701
- Release Information | 15701

Syntax

```
retry-count number;
```

Hierarchy Level

```
[edit chassis cluster redundancy-group group-number ip-monitoring]
```

Description

Specify the number of consecutive ping attempts that must fail before an IP address monitored by the redundancy group is declared unreachable in IP address monitoring.

In the IP address monitoring, you can configure redundancy groups to monitor upstream resources by pinging specific IP addresses that are reachable through redundant Ethernet interfaces on either node in a cluster. In this configuration, the retry interval determines the ping interval for each IP address monitored by the redundancy group and the retry count sets the number of allowed consecutive ping failures for each IP address monitored by the redundancy group.

(See "retry-interval (Chassis Cluster)" on page 15707 for a related redundancy group IP address monitoring variable.)

Options

number—Number of consecutive ping attempt failures before a monitored IP address is declared unreachable.

- **Default:** 5
- **Range:** 5-15

Required Privilege Level

}
```

Syntax (Junos OS Evolved)

```
retry-options {
    lockout-period minutes;
}
```

Hierarchy Level

```
[edit system login]
```

Description

Limit the number of times a user can attempt to log in through SSH or Telnet before being disconnected.

Options

backoff-factor *seconds*

Length of delay in seconds after each failed login attempt. The length of delay increases by this value for each subsequent failed login attempt after the value specified in the `backoff-threshold` option.

- **Default:** 5
- **Range:** 5 through 10

backoff-threshold *number*

Threshold for the number of failed login attempts before the user experiences a delay when attempting to log in again. Use the `backoff-factor` option to specify the length of delay, in seconds.

- **Default:** 2
- **Range:** 1 through 3

lockout-period *minutes*

Amount of time before the user can attempt to log in to the device after being locked out. The user is locked out when the number of failed login attempts specified in the `tries-before-disconnect` option is reached.

- **Range:** 1 through 43200

maximum-time *seconds*

Maximum length of time that the connection remains open for the user to enter a username and password to log in. If the user remains idle and does not enter a username and password within the time period configured with this option, the connection is closed.

- **Default:** 120
- **Range:** 20 through 300

minimum-time *seconds*

Minimum length of time that the connection remains open while the user is attempting to enter a username and password to log in.

- **Default:** 20
- **Range:** 20 through 60

tries-before-disconnect

Maximum number of times a user is allowed to attempt to log in through SSH or Telnet before closing the connection.

- **Default:** 3
- **Range:** 2 through 10

Required Privilege Level

- Release Information | 15723

Syntax

```
reverse-tcp-mss mss-value;
```

Hierarchy Level

```
[edit security policies from-zone zone-name to-zone zone-name
policy policy-name then permit tcp-options]
```

Description

Configure the TCP maximum segment size (MSS) for packets that match a specific policy and travel in the reverse direction of a session. The value you configure replaces the TCP MSS value when the value in the packet is higher than the one you specify.

The `reverse-tcp-mss` value per policy takes precedence over a global `tcp-mss` value (`all-tcp`, `ipsec-vpn`, `gre-in`, `gre-out`), if one is configured. However, when the `syn-flood-protection-mode syn-proxy` statement at the `[edit security flow] hierarchy level` is used to enable SYN proxy defenses against SYN attacks, the TCP MSS value is not overridden.

Because each policy has two directions, you can configure a value for both directions or for just one direction. To configure the TCP MSS value for the initial session, use the `initial-tcp-mss` option.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

revert-time (Protocols Layer 2 Circuits)

IN THIS SECTION

Syntax | 15730

Hierarchy Level | 15730

- Description | 15730
- Default | 15731
- Options | 15731
- Required Privilege Level | 15731
- Release Information | 15732

Syntax

```
revert-time seconds maximum seconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols l2circuit neighbor address interface
interface-name],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols vpls
neighbor address],
[edit protocols l2circuit neighbor address interface interface-name],
[edit routing-instances routing-instance-name protocols vpls neighbor address]
```

Description

Specify a revert time for redundant Layer 2 circuits and VPLS pseudowires. When you have configured redundant pseudowires for Layer 2 circuits or VPLS, traffic is switched to the backup connection in the event that the primary connection fails. If you configure a revert time, when the configured time expires traffic is reverted to the primary path, assuming the primary path has been restored.

With the `maximum` option, specify a maximum reversion interval to add after the `revert-time` delay. If a revert-time delay is defined but a maximum timer is not defined, VCs are restored upon the revert-timer's expiration.

To reduce as much as possible the amount of traffic discarded, and potential data-path asymmetries observed during primary-to-backup transition periods, you can use this restoration timer. This restoration timer is activated when the backup path is performing as active, and then the primary path is restored. The goal is to avoid moving traffic back to the primary path right away, to make sure that the control plane's related tasks (such as IGP, LDP, RSVP, and internal BGP) have enough time to complete their updating cycle.

By enabling a gradual return of traffic to the primary path, you can ensure that the relatively-slow control-plane processing and updating does not have a negative impact on the restoration process.

The `maximum` option extends the revert timer's functionality to provide a jittered interval over which a certain number of circuits can be transitioned back to the primary path. By making use of this maximum value, you can define a time interval during which circuits are expected to switch over. As a consequence, circuits' effective transitions are scattered during restoration periods.

When making use of `revert-time` *`x`* `maximum` *`y`* statement, you can ensure that the corresponding circuit that is active is moved to the primary path within a time-slot (t1) such as that: x <= t1 <= y. In other words, by activating this statement, you can ensure the following:

- VCs stay in the backup path for at least x seconds after the primary path comes back up.
- VCs are moved back to the primary path before y seconds have elapsed.
- y maximum value = x maximum value * 2 = 7200 seconds.

The ideal values for x and y will are conditioned to internal aspects of your network. For this reason, there are no default values for these settings. If no revert-time is set, the default behavior is non-revertive. That is, circuits are not returned to the primary path upon restoration. They are kept on the backup path.

Default

Without the `revert-time` statement, virtual circuit (VC) traffic is not transitioned to the primary path upon restoration of the primary path.

Options

seconds—Revert time in seconds.

- **Range:** 0 through 3600 seconds

maximum *seconds*—Number of seconds to delay path restoration after the `revert-time` delay.

- **Range:** 0 through 7200 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.2.

`maximum` option introduced in Junos OS Release 13.2.

The range and maximum range for revert-time increased from 600 to 3600 and 1200 to 7200 seconds in Junos OS Release 23.1R1.

[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name],
```

```
[edit protocols mpls],
[edit protocols mpls label-switched-path lsp-name]
```

Description

Specify the amount of time (in seconds) that an LSP must wait before traffic reverts to a primary path. If during this time the primary path experiences any connectivity problem or stability problem, the timer is restarted.

If you have configured BFD on the LSP, the Junos OS waits until the BFD session is restored before starting the revert timer counter.

If you have configured a value of 0 seconds for the `revert-timer` statement and traffic is switched to the secondary path, the traffic remains on that path indefinitely. It is never switched back to the primary path unless you intervene.

Options

seconds—Time in seconds.

- **Range:** 0 through 65,535 seconds
- **Default:** 60 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

revocation-check {
    disable;
    crl {
        refresh-interval number-of-hours;
        url {
            url-name;
        }
    }
}
```

Hierarchy Level

```
[edit security pki ca-profile ca-profile-name]
```

Description

Specify the method to verify revocation status of digital certificates for J Series Services Routers and Adaptive Services (AS) and MultiServices PICs installed in M Series and T Series routers.

Options

`disable`—Disable verification of status of digital certificates. Use `disable` temporarily in cases where a certificate authority (CA) server is unreachable and certificate cannot be renewed or if the certificate download fails.

`crl`—Only certificate revocation list (CRL) is supported. A CRL is a time-stamped list identifying revoked certificates, which is signed by a CA and made available to the participating IPsec peers on a regular periodic basis. By default, `crl` is enabled.

The PKID process might fail after RG0 failover on the new node causing all the IPsec VPNs using the public key infrastructure (PKI) to go down when:

- A local certificate used for IPsec VPN is revoked by the Certificate Authority (CA).
- Certificate revocation list (CRL) check is disabled.
- CRL is not cleared.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

- Syntax | 15739
- Hierarchy Level | 15739
- Description | 15739
- Options | 15740
- Required Privilege Level | 15740
- Release Information | 15741

Syntax

```
revocation-check {
    crl:
    disable;
    ocsp:
    use-crl;
    use-ocsp;
}
```

Hierarchy Level

```
[edit security pki ca-profile ca-profile-name]
```

Description

Specify the method the device uses to verify the revocation status of digital certificates.

Options

crl Only certificate revocation list (CRL) is supported. A CRL is a time-stamped list identifying revoked certificates, which is signed by a CA and made available to the participating IPsec peers on a regular periodic basis.

You should also specify the location (URL) to retrieve the CRL (HTTP or LDAP). By default, the URL is empty and uses CDP information embedded in the CA certificate.

For Example: `set security pki ca-profile ms-ca revocation-check crl url http://labsrv1.labdomain.com/CertEnroll/LABDOMAIN.crl`

The URL can include the server-name or port information such as, ldap://<ip-or-fqdn>:<port>). If the port number is missing, HTTP uses port 80, or LDAP uses port 443. Currently, you can configure only one URL. We do not support for configuring backup URL.

By default, `crl` is enabled. Local certificates are being validated against certificate revocation list (CRL) even when CRL check is disabled. This can be stopped by disabling the CRL check through the Public Key Infrastructure (PKI) configuration. When CRL check is disabled, PKI will not validate local certificate against CRL.

disable Disable verification of status of digital certificates.

ocsp Configure Online Certificate Status Protocol (OCSP) to check the revocation status of a certificate.

use-crl Specify the CRL as the method to check the revocation status of a certificate. CRL is the default method.

When you enable this option, you choose CRL as a method to verify the revocation status of digital certificates.

use-ocsp Specify the Online Certificate Status Protocol (OCSP) as the method to check the revocation status of a certificate. CRL is the default method.

When you enable this option, you choose OCSP as a method to verify the revocation status of digital certificates.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement modified in Junos OS Release 8.5. Support for `ocsp`, `use-crl`, and `use-ocsp` options added in Junos OS Release 12.1X46-D20.

rewrite-rules (Definition)

IN THIS SECTION

- Syntax | 15746
- Hierarchy Level | 15747
- Description | 15747
- Options | 15747
- Required Privilege Level | 15747
- Release Information | 15747

Syntax

```
rewrite-rules {
    type rewrite-name {
        import (rewrite-name | default);
        forwarding-class class-name {
            loss-priority level code-point [ aliases ] [ bit-patterns ];
        }
    }
}
```

Hierarchy Level

```
[edit class-of-service]
```

Description

Specify a rewrite-rules mapping for the traffic that passes through all queues on the interface.

Options

rewrite-name—Name of a `rewrite-rules` mapping.

type—Traffic type.

- **Values:** `dscp`, `dscp-ipv6`, `exp`, `ieee-802.1`, `ieee-802.1ad`, `inet-precedence`, `inet6-precedence`

The remaining statements are explained separately. See CLI Explorer.

    inet-precedence (rewrite-name | default) protocol (inet-both | inet-outer | mpls);
}
```

Hierarchy Level

```
[edit class-of-service interfaces interface-name],
[edit class-of-service interfaces interface-name unit logical-unit-number]
```

Description

Associate a rewrite-rules configuration or default mapping with a specific interface.

Integrated Bridging and Routing (IRB) interfaces are used to tie together Layer 2 switched and Layer 3 routed domains on MX routers. MX routers support classifiers and rewrite rules on the IRB interface at the `[edit class-of-service interfaces irb unit logical-unit-number]` level of the hierarchy. All types of classifiers and rewrite rules are allowed, including IEEE 802.1p.

> **NOTE**: The IRB classifiers and rewrite rules are used only for *routed* packets; in other words, it is for traffic that originated in the Layer 2 domain and is then routed through IRB into the Layer 3 domain, or vice versa. Only IEEE classifiers and IEEE rewrite rules are allowed for pure Layer 2 interfaces within a bridge domain.

On an MX Series router and on an EX Series switch, `exp-push-push-push`, `exp-swap-push-push`, and `frame-relay-de` are not supported on an integrated routing and bridging (IRB) interface.

The `[edit class-of-service interfaces interface-name unit logical-unit-number]` hierarchy level is not supported on ACX Series routers.

On an ACX Series router, only the outer tag is supported for `dscp`, `inet-precedence`, and `ieee802.1`.

For IQ PICs, you can configure only one IEEE 802.1 rewrite rule on a physical port. All logical ports (units) on that physical port should apply the same IEEE 802.1 rewrite rule.

Options

`rewrite-name`—Name of a `rewrite-rules` mapping configured at the `[edit class-of-service rewrite-rules]` hierarchy level.

`default`—The default mapping.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Configuring Rewrite Rules

rewrite-rules (Definition) | **15746**

Applying Rewrite Rules to Output Logical Interfaces

rewrite-value (Fibre Channel Interfaces)

IN THIS SECTION

- Syntax | **15753**
- Hierarchy Level | **15753**
- Description | **15753**
- Required Privilege Level | **15754**

Syntax

```
rewrite-value {
    input {
        ieee-802.1{
            code-point code-point-bits;
        }
    }
}
```

Hierarchy Level

```
[edit class-of-service interfaces fibre-channel-interface-name]
```

Description

Configure the IEEE 802.1p code point value (priority) for all traffic received from the Fibre Channel (FC) network on the specified FC interface. Instead of using the default priority 3 (011) for FCoE traffic, the

priority is rewritten to the specified priority before being forwarded. This works in conjunction with configuring a fixed classifier on the FC interface. The fixed classifier maps all traffic from the FC network into one lossless forwarding class (the lossless forwarding class must be mapped to the code point specified in the rewrite value). Traffic mapped to the lossless forwarding class uses the IEEE 802.1p priority specified by the code point bits in the rewrite value.

FCoE traffic typically uses priority 3 (IEEE code point 011). The QFX Series default configuration uses IEEE 802.1p priority 3 for FCoE traffic. Rewriting the code point value enables you to change the IEEE 802.1p priority of the FCoE traffic if the Ethernet network uses a different priority than priority 3 (code point 011) for FCoE traffic.

The system supports only one IEEE 802.1p code point value per FC interface, so you cannot configure more than one IEEE 802.1p rewrite value per FC interface. In addition, you can specify only one rewrite value per local FCoE-FC gateway fabric; all interfaces in the local fabric must use the same rewrite value. Attempting to configure FC interfaces in the same local fabric with different rewrite values generates a commit error. You can specify different rewrite values for interfaces that belong to different local FCoE-FC gateway fabrics.

NOTE: In order to avoid fate sharing (separate flows that affect each others' throughput), the code point used for the rewrite value should be the only code point used for the lossless FCoE forwarding class (the forwarding class used for the fixed classifier on the Fibre Channel interface). When you configure classifiers for ingress Ethernet interfaces, map only the rewrite value code point to the forwarding class.

For example, if the rewrite value uses code point 101 for lossless FCoE forwarding class fcoe_fc1, then in the classifier configuration attached to ingress Ethernet interfaces, code point 101 is the only code point that should be classified to the fcoe_fc1 forwarding class. Now if you also attach a classifier to an interface that maps code point 110 to forwarding class fcoe_fc1, then congestion on priority 110 unfairly (and unintentionally) affects the FCoE traffic that uses priority 101. Both priorities 101 and 110 are classified into forwarding class fcoe_fc1, so the traffic from both priorities shares the same fate.

The remaining statements are described separately.

rfc-compliant (NETCONF)

IN THIS SECTION

- Syntax | 15755
- Hierarchy Level | 15755
- Description | 15755
- Default | 15756
- Required Privilege Level | 15757
- Release Information | 15757

Syntax

```
rfc-compliant;
```

Hierarchy Level

```
[edit system services netconf]
```

Description

Require that the NETCONF server enforce certain behaviors that are compliant with RFC 4741, *NETCONF Configuration Protocol*, during NETCONF sessions.

When you configure the `rfc-compliant` statement:

- The NETCONF server explicitly declares the NETCONF namespace in its replies and qualifies all NETCONF tags with the `nc` prefix.

- <get> and <get-config> operations that return no configuration data do not include an empty <configuration> element in RPC replies.
- On devices running Junos OS Release 17.2R1 or later, the NETCONF server sets the default namespace for the <configuration> element to the same namespace as in the corresponding YANG model.
- On devices running Junos OS Release 17.4R3, 18.2R2, 18.3R2, and 18.4R1 or later, the NETCONF server omits <rpc-error> elements with a severity level of warning in its replies when the operation is successful and returns an <ok/> element.
- On devices running Junos OS Release 21.2R1 or later, the NETCONF server's response to <commit> operations includes the following changes:
  - If a successful <commit> operation returns a response with one or more warnings, the warnings are redirected to the system log file, in addition to being omitted from the response.
  - The NETCONF server response emits the <source-daemon> element as a child of the <error-info> element instead of the <rpc-error> element.
  - If you also configure the flatten-commit-results statement at the [edit system services netconf] hierarchy level, the NETCONF server suppresses any <commit-results> XML subtree and only emits an <ok/> or <rpc-error> element in its response.
- On devices running Junos OS Release 23.2R1 or later and on devices running Junos OS Evolved Release 23.4R1 or later, the NETCONF server emits only an <ok/> or <rpc-error> element in response to <validate> operations. In earlier releases, the RPC reply also includes the <commit-results> element.

Default

If you do not include the rfc-compliant statement:

- The NETCONF server sets the default namespace to the NETCONF namespace in RPC replies.
- <get> and <get-config> operations that return no configuration data include an empty <configuration> element in RPC replies.
- The NETCONF server does not set the default namespace for the <configuration> element to the same namespace as in the corresponding YANG model.
- The NETCONF server might issue an RPC reply that includes both an <rpc-error> element with a severity level of warning and an <ok/> element.
- The NETCONF server's response to <commit> and <validate> operations might not be RFC compliant.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Description

Create a routing table.

Explicitly creating a routing table with ***routing-table-name*** is optional if you are not adding any static, martian, aggregate, or generated routes to the routing table and if you also are creating a routing table group.

> **NOTE**: The IPv4 multicast routing table (**inet.1**) and the IPv6 multicast routing table (**inet6.1**) are not supported for this statement.

Default

If you do not specify a routing table name with the ***routing-table-name*** option, the software uses the default routing tables, which are **inet.0** for unicast routes and **inet.1** for the multicast cache.

Options

routing-table-name—Name of the routing table, in the following format: ***protocol***[.***identifier***].

In a routing instance, the routing table name must include the routing instance name. For example, if the routing instance name is **link0**, the routing table name might be **link0.inet6.0**.

- ***protocol*** is the protocol family. It can be **inet6** for the IPv6 family, **inet** for the IPv4 family, **iso** for the ISO protocol family, or ***instance-name*.iso.0** for an ISO routing instance.
- ***identifier*** is a positive integer that specifies the instance of the routing table.
- **Default: inet.0**

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

`policy-multipath` statement introduced in Junos Release 19.1R1 for all platfroms.

rib-group (Protocols DVMRP)

IN THIS SECTION

- Syntax | 15769
- Hierarchy Level | 15769
- Description | 15770
- Options | 15770
- Required Privilege Level | 15770
- Release Information | 15770

Syntax

```
rib-group group-name;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols dvmrp],
[edit protocols dvmrp]
```

Description

Associate a routing table group with DVMRP.

Options

group-name—Name of the routing table group. The name must be one that you defined with the `rib-groups` statement at the `[edit routing-options]` hierarchy level.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

> **NOTE**: Distance Vector Multicast Routing Protocol (DVMRP) was deprecated in Junos OS Release 16.1. Although DVMRP commands continue to be available and configurable in the CLI, they are no longer visible and are scheduled for removal in a subsequent release.

Statement introduced before Junos OS Release 7.4.

    }
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options],
[edit routing-options]
```

Description

Group one or more routing tables to form a routing table group. A routing protocol can import routes into all the routing tables in the group and can export routes from a single routing table.

Each routing table group must contain one or more routing tables that Junos OS uses when importing routes (specified in the `import-rib` statement) and optionally can contain one routing table group that Junos OS uses when exporting routes to the routing protocols (specified in the `export-rib` statement).

The first routing table you specify is the *primary routing table*, and any additional routing tables are the *secondary routing tables*.

The primary routing table determines the address family of the routing table group. To configure an IP version 4 (IPv4) routing table group, specify **inet.0** as the primary routing table. To configure an IP version 6 (IPv6) routing table group, specify **inet6.0** as the primary routing table. If you configure an IPv6 routing table group, the primary and all secondary routing tables must be IPv6 routing tables (**inet6.*x***).

In Junos OS Release 9.5 and later, you can include both IPv4 and IPv6 routing tables in an IPv4 import routing table group using the `import-rib` statement. In releases prior to Junos OS Release 9.5, you can only include either IPv4 or IPv6 routing tables in the same `import-rib` statement. The ability to configure an import routing table group with both IPv4 and IPv6 routing tables enables you, for example, to populate the **inet6.3** routing table with IPv6 addresses that are compatible with IPv4. Specify **inet.0** as the primary routing table, and specify **inet6.3** as a secondary routing table.

NOTE: On EX Series switches, only dynamically learned routes can be imported from one routing table group to another.

NOTE: If you configure an import routing table group that includes both IPv4 and IPv6 routing tables, any corresponding export routing table group must include only IPv4 routing tables.

If you have configured a routing table, configure the OSPF primary instance at the `[edit protocols ospf]` hierarchy level with the statements needed for your network so that routes are installed in **inet.0** and in the forwarding table. Make sure to include the routing table group. For more information, see *Example: Configuring Multiple Routing Instances of OSPF*.

After specifying the routing table from which to import routes, you can apply one or more policies to control which routes are installed in the routing table group. To apply a policy to routes being imported into the routing table group, include the `import-policy` statement.

Options

group-name—Name of the routing table group. The name must start with a letter and can include letters, numbers, and hyphens.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

[edit logical-systems logical-system-name routing-instances routing-instance-name routing-
options],
[edit routing-instances routing-instance-name routing-options],
[edit routing-options]
```

Description

Configure a static route to install routes in the routing table for a specific topology.

Options

routing-table-name—Name of the routing table for a topology. Use the following format: ***logical-system-name/ routing-instance-name:topology-name.protocol.identifier***. Include the routing instance string only if the instance is not the primary. The logical system string is included only if the logical system identifier has a value other than 0 (zero). Each routing table for a topology includes a colon (:) before the topology name. ***protocol*** is the protocol family, which can be **inet** or **inet6**. ***identifier*** is the positive integer that specifies the instance of the routing table. For example, to install IPv6 routes to the routing table for a topology named voice in the primary instance, include **:voice.inet6.0**.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement support for multitopology routing introduced in Junos OS Release 9.0.

Statement introduced in Junos OS Release 9.0.

Syntax

```
rib-service {
    dynamic-next-hop-interface (enable | disable);
}
```

Hierarchy Level

```
[edit routing-options programmable-rpd]
```

Description

Configure programmable routing protocol process (prpd) options that apply only to the RIB Service API.

Options

dynamic-next-hop-interface (enable | disable)

Disable or enable dynamic next-hop interface binding. When enabled, programmed RIB routes react to Up, Down, Add, and Delete events for direct next-hop interfaces. When all next-hop interfaces are unconfigured or down, the route is hidden and becomes inactive. When a next-hop interface is configured or comes up, the route becomes visible and active. This prevents dropped traffic and keeps inactive routes from being propagated through the network.

This feature applies to all routes programmed using the rib_service JET API where an interface is configured as a direct next-hop, including interfaces that are part of a flexible tunnel. It also applies to tunnels configured with the flexible_tunnel_service JET API. Indirect next-hops are resolved by the RPD resolver normally.

Changes to the configuration of this statement only affect routes programmed using Junos OS Release 20.2R1 or later.

- **Default:** This option is enabled by default starting in Junos OS Release 20.2R1. In earlier releases, dynamic next-hop interface binding is disabled by default.

Required Privilege Level

routing

Release Information

Statement introduced in Junos OS Release 20.2R1.

rib-sharding

IN THIS SECTION

- Syntax | 15792
- Hierarchy Level | 15792
- Description | 15792
- Options | 15793
- Required Privilege Level | 15793
- Release Information | 15793

Syntax

```
rib-sharding {
    number-of-shards;
}
```

Hierarchy Level

```
[edit system processes routing bgp]
```

Description

Enable BGP RIB sharding. BGP RIB sharding is to split the BGP process across routes. Different routes are hashed into different threads to achieve concurrency. BGP RIB sharding splits a unified BGP RIB into several sub RIBs and each sub RIB handles a subset of BGP routes. Each sub RIB is served by a separate RPD thread to achieve concurrency. BGP RIB sharding is disabled by default. To enable, you need to explicitly configure it on a multicore routing engine. This feature is supported only on 64-bit routing protocol process (rpd) where the Routing Engine has more than one core. We recommend configuring this feature on a device with atleast 4CPU cores and 16GB of memory.

NOTE:

- RPD would restart automatically when rib-sharding or update-threading configuration is changed.
- Sharding requires Update/IO thread. If `rib-sharding` is configured and `update-threading` is not configured, the commit check fails.
- BGP RIB sharding and update IO features are supported for the following IPv4 and IPv6 address families:
  - IPv4 VPN Unicast
  - IPv4 VPN Multicast (vrf.inet.2)
  - IPv6 VPN Unicast
  - IPv6 VPN Multicast (vrf.inet.2)
  - IPv4 Labeled Unicast
  - IPv6 Labeled Unicast
- All the other RIBs are still processed without sharding.

Options

`number of shards`—the number of sharding threads created. If you configure `rib-sharding` on a routing engine, RPD creates sharding threads. By default, it is the same as the number of CPU cores on the routing engine. Optionally, you can specify the number-of-shards you want to create.

- **Range:** 1-31 shards

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 19.4R1.

Support for NSR with sharding introduced in Junos OS Release 22.2.

BGP sharding supports IPv4, IPv6, L3VPN and BGP-LU from Junos OS Release 20.4R1.

```

Description

Configure the Routing in Fat Trees (RIFT) protocol for IP abrics that have CLOS-based and fat tree model topologies.

The RIFT protocol enables:

- Automatic disaggregation of prefixes on link and node failures.
- Minimal storing of routing state information at every level.
- Zero-configuration capabilities with automatic pruning.
- Load balancing of traffic towards the spine based on available bandwidth.
- Synchronization of a limited key-value data-store that can be used after protocol convergence.

Options

capabilities

Enable the RIFT capability of reducing flooding globally. See "capabilities" on page 3197 for more information.

deafult-prefixes

Explicitly specify default prefixes generated in southbound direction. See "default-prefixes" on page 5206 for more information.

default-prefixes-advertisement (always | never)

(Optional) Enable default route generation strategy.

- always—Always originate default prefixes southbound.
- never—Never originate default prefix southbound.

export

Enable exporting of routes from other protocols into the RIFT protocol. See "export" on page 6685 for more information.

external-preference ***external-preference***

—(Optional) External route preference for the RIFT protocol. The external preference configured is analogous to the OSPF configuration. This value is shown when RIFT installs the preference as static route values.

- **Range:** 1 through 256

interface

(Optional) Configure the interfaces for the RIFT protocol. See "interface" on page 8994 for more information.

level

(Optional) Configure the level to identify the role of node in the RIFT topology. See "level" on page 9734 for more information.

lie-receive-address

(Optional) Configure the address on which the link information elements (LIEs) should be received. See "lie-receive-address" on page 9742 for more information.

lie-receive-port ***port-number***

(Optional) Port on which link information elements (LIES) should be received.

- **Range:** 512 through 65535

name ***name***

(Optional) Name of the node for identification.

node-id (*node-id* | auto)

(Optional) ID of the configured node, or enable zero touch provisioning where the node ID is configured automatically.

overload

(Optional) Configure the overload bit that takes the node out of traffic bearing paths.

- Values:

  timeout seconds (Optional) Specify in seconds the time after which the overload bit is reset. The overload timeout is similar to IS-IS timeout.

  - **Range:** 10 through 1800 seconds

preference ***route-preference***

(Optional) Route preference for the RIFT protocol.

- **Range:** 15 through 256

proxy-process

(Optional) Configure the proxy process options for the RIFT protocol.

tie-authentication (loose | none | permissive | strict)

(Optional) Configure the method to authenticate received TIEs (inner fingerprint).

- Values:

  loose Verify authentication only if present, that is, when the key ID is not 0.

  none Disable authentication checking completely.

permissive Accept authentication if key identifier is unknown.

strict Accept authentication only if a key is present and it is valid.

tie-origination-key *tie-origination-key* (Optional) Configure the key ID used to protect self-originated TIEs (inner key).

- **Range:** 1 through 16777215

traceoptions (Optional) Enable traceoptions for the RIFT protocol.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 19.4R1.

riot-loopback

IN THIS SECTION

- Syntax | 15801
- Hierarchy Level | 15802
- Description | 15802
- Required Privilege Level | 15802
- Release Information | 15802

Syntax

```
riot-loopback;
```

Hierarchy Level

```
[edit vlans name vxlan]
```

Description

Assign a VLAN that enables routing in and out of VXLAN tunnels (RIOT) for symmetric EVPN Type 2 and Type 5 routing.

Some Juniper switching platforms don't have native VXLAN routing hardware support for Layer 3 VXLAN gateway functions. Instead, supporting switches can use an intermediary loopback port in a two-pass process for routing in and out of VXLAN tunnels (RIOT). You configure this intermediary port as a loopback link aggregation group (LAG) that is a member of all VLANs with IRB interfaces used for VXLAN routing.

To support symmetric EVPN Type 2 and Type 5 routes with the RIOT loopback LAG port, for each Layer 3 virtual routing and forwarding (VRF) instance, you:

- Configure an extra VLAN with an IRB interface.
- Map that VLAN to the same VXLAN network identifier (VNI) that you configure for a corresponding Layer 3 VRF instance.
- Configure this `riot-loopback` statement with the extra VLAN so the Layer 3 VRF instance uses the RIOT loopback LAG port for Type 2 and Type 5 VXLAN routing.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced for EVPN Type 5 routing in Junos OS Release 21.3R1.

Support added for symmetric EVPN Type 2 routing in Junos OS Release 21.4R1.

Syntax

```
rng [dyce | fortuna | hmac-drbg];
```

Hierarchy Level

```
[edit system]
```

Description

Configure a system cryptographically secure pseudo-random number generator (CSPRNG). By default, rng is not configured.

NOTE:

- Only root users can configure rng options.
- A device reboot is required for the change to take effect.
- In FIPS mode, HMAC-DRBG will be the only active RNG available.

Default

Federal Information Processing Standards (FIPs) and Non-FIPs mode behavior:

- (SRX1500, SRX4100, SRX4200, and SRX4600 Devices) FIPS Mode uses the hash-based message authentication code-deterministic random bit generator (HMAC-DRBG) , while Non-FIPS mode uses the Junos default Fortuna Random Number Generator.
- (General Routing) Starting with Junos OS Release 21.4R1, in non-FIPS mode, the RNG in FreeBSD 12 based Junos OS versions has been changed from the default FreeBSD Fortuna RNG to the FIPS/SP800-90A&B HMAC-DRBG CSPRNG.

Options

fortuna Configure the fortuna CSPRNG.

hmac-drbg Configure the HMAC DRBG CSPRNG.

dyce Configure the Da Yan Concentrator and Extender of Random Data (DYCE) CSPRNG.

Required Privilege Level

system-To view this statement in the configuration.

[edit bridge-domains bridge-domain-name protocols igmp-snooping interface interface-name],
[edit bridge-domains bridge-domain-name protocols igmp-snooping vlan vlan-id interface interface-name],
[edit routing-instances routing-instance-name bridge-domains bridge-domain-name protocols igmp-snooping interface interface-name],
[edit routing-instances routing-instance-name bridge-domains bridge-domain-name protocols igmp-snooping vlan vlan-id interface interface-name],
[edit protocols igmp-snooping vlan vlan-name]
```

Description

Configure the number of queries a device sends before removing a multicast group from the multicast forwarding table. We recommend that the robust count be set to the same value on all multicast routers and switches in the VLAN.

This option provides fine-tuning to allow for expected packet loss on a subnet. You can wait more intervals if subnet packet loss is high and IGMP report messages might be lost.

Use the `query-interval`, `query-last-member-interval`, or `query-response-interval` statements in the same hierarchy to configure interval lengths.

Options

number—Number of intervals the switch waits before timing out a multicast group.

- **Range:** 2 through 10
- **Default:** 2

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.5.

interface (Protocols PIM)  interface-name bidirectional df-election],
[edit protocols pim interface (Protocols PIM)  interface-name bidirectional df-election],
[edit routing-instances routing-instance-name protocols pim interface (Protocols PIM)  interface-
name bidirectional df-election]
```

Description

Configure the designated forwarder (DF) election robustness count for bidirectional PIM. When a DF election Offer or Winner message fails to be received, the message is retransmitted. The **robustness-count** statement sets the minimum number of DF election messages that must fail to be received for DF election to fail. To prevent routing loops, all routers on the link must have a consistent view of the DF. When the DF election fails because DF election messages are not received, forwarding on bidirectional PIM routes is suspended.

If a router receives from a neighbor a better offer than its own, the router stops participating in the election for a period of **robustness-count** * **offer-period**. Eventually, all routers except the best candidate stop sending Offer messages.

Options

number—Number of transmission attempts for DF election messages.

- **Range:** 1 through 10
- **Default:** 3

Required Privilege Level

role

IN THIS SECTION

- Syntax | **15825**
- Hierarchy Level | **15825**
- Description | **15825**
- Options | **15826**
- Required Privilege Level | **15827**

Release Information | 15827

Syntax

```
role (line-card | routing-engine);
```

Hierarchy Level

```
[edit virtual-chassis member member-id]
```

Description

Specify the roles of the members of the Virtual Chassis or a Virtual Chassis Fabric (VCF) in a preprovisioned Virtual Chassis. For a mixed Virtual Chassis or VCF, see Understanding Mixed EX Series and QFX Series Virtual Chassis or *Understanding Mixed Virtual Chassis Fabric* for any recommendations or requirements for assigning the Routing Engine role based on the types of switches comprising the Virtual Chassis or VCF.

Virtual Chassis Fabric

Specify the role to be performed by each switch. In a VCF, two spine devices are configured into the Routing Engine role and the remaining spine devices and all leaf devices are configured into the `line-card` role. The role must also be associated with the member's serial number (see "serial-number" on page 16599).

EX Series (except EX8200 Virtual Chassis) and QFX Series Virtual Chassis

Specify the role to be performed by each member switch. Associate the role with the member's serial number (see "serial-number" on page 16599).

When you use a preprovisioned configuration, you cannot modify the primary-role priority or member ID of member switches through the user interfaces. The primary-role priority value is generated by the software, based on the assigned role:

- A member configured as `routing-engine` is assigned the primary-role priority 129.
- A member configured as `line-card` is assigned the primary-role priority 0.

- A member listed in the preprovisioned configuration without an explicitly specified role is assigned the `line-card` role and primary-role priority 0 by default.

The configured role specifications are permanent. If both `routing-engine` members fail, a `line-card` member cannot take over as primary of the Virtual Chassis configuration. You must delete the preprovisioned configuration to change the specified roles in a Virtual Chassis.

Explicitly configure two members as `routing-engine` and configure additional switches as members of the preprovisioned Virtual Chassis by specifying only their serial numbers. If you do not explicitly configure the role of the additional members, they function in a `line-card` role by default. In that case, a member that is functioning in a `line-card` role can take over primary role if the members functioning as primary and backup (`routing-engine` role) both fail.

EX8200 Virtual Chassis

Specify the role to be performed by each XRE200 External Routing Engine and each EX8200 member switch. Associate the role with the member's serial number (see "serial-number" on page 16599). An EX8200 Virtual Chassis cannot function when both external Routing Engines, which must be configured in the `routing-engine` role, have failed.

Options

- `line-card`—Enables the member to be eligible to function only in the linecard role. Any member of the Virtual Chassis or VCF configuration other than the primary or backup functions in the linecard role and runs only a subset of Junos OS for EX Series switches. A member functioning in the linecard role does not run the control protocols or the chassis management processes.

  A Virtual Chassis must have at least three members for one member to function in the linecard role.

  In an EX8200 Virtual Chassis configuration, all member switches must be in the linecard role.

- `routing-engine`—Enables the member to function as a primary or backup Routing Engine of the Virtual Chassis or VCF configuration. The primary manages all members and runs the chassis management processes and control protocols. The backup synchronizes with the primary in terms of protocol states, forwarding tables, and so forth, so that it is prepared to preserve routing information and maintain network connectivity without disruption in case the primary is unavailable.

  In a Virtual Chassis composed of EX Series switches (except EX8200 switches) or QFX Series switches, specify two and only two members in the `routing-engine` role. The software determines which of the two members assigned the `routing-engine` role functions as primary, based on the primary-role election algorithm. See Understanding How the Primary in a Virtual Chassis Is Elected. In these Virtual Chassis, the `routing-engine` role is associated with a switch. For a mixed Virtual Chassis or VCF, see Understanding Mixed EX Series and QFX Series Virtual Chassis or *Understanding Mixed Virtual Chassis Fabric* for specific recommendations or requirements for assigning the Routing Engine

role based on the types of switches comprising the Virtual Chassis or VCF. The remaining switches are configured into the linecard role.

In an EX8200 Virtual Chassis, all XRE200 External Routing Engines must be in the `routing-engine` role.

Required Privilege Level

system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.0.

role (MX Series Virtual Chassis)

IN THIS SECTION

- Syntax | **15828**
- Hierarchy Level | **15828**
- Description | **15828**
- Options | **15828**
- Required Privilege Level | **15828**
- Release Information | **15829**

Syntax

```
role (routing-engine | line-card);
```

Hierarchy Level

```
[edit virtual-chassis member member-id]
```

Description

As part of the preprovisioned configuration for an MX Series Virtual Chassis, assign the role to be performed by each member router in the Virtual Chassis. The preprovisioned configuration permanently associates the member ID and role with the member router's chassis serial number.

Options

routing-engine—Enable the member router to function as the primary router or backup router of the Virtual Chassis configuration. The primary router maintains the global configuration and state information for both members of the Virtual Chassis, and runs the chassis management processes. The backup router synchronizes with the primary router and relays chassis control information, such as line-card presence and alarms, to the primary router. If the primary router is unavailable, the backup router takes primary role of the Virtual Chassis to preserve routing information and maintain network connectivity without disruption. You must assign the **routing-engine** role to both members of the Virtual Chassis. When the Virtual Chassis is formed, the software runs a primary-role election algorithm to determine which of the two member routers functions as the primary router and which functions as the backup router of the Virtual Chassis.

line-card—Explicitly configuring a member router with the **line-card** role is *not supported* in the current release. However, when split detection is enabled (the default behavior for a Virtual Chassis) and either the Virtual Chassis ports go down or the backup router fails, the primary router takes a **line-card** role. The **line-card** role effectively removes the former primary router from the Virtual Chassis configuration until connectivity is restored.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.2.

rollback

IN THIS SECTION

- Syntax | 15831
- Description | 15831
- Options | 15831
- Required Privilege Level | 15831
- Release Information | 15831

Syntax

```
rollback <number | rescue | revision revision-string>
```

Description

Return to a previously committed configuration. The software saves the last 50 committed configurations, including the rollback number, date, time, and name of the user who issued the `commit` configuration command.

The currently operational configuration is stored in the file **juniper.conf**, and the last three committed configurations are stored in the files **juniper.conf.1**, **juniper.conf.2**, and **juniper.conf.3**. These four files are located in the directory **/config**, which is on the router's flash drive. The remaining 46 previous committed configurations, the files **juniper.conf.4** through **juniper.conf.49**, are stored in the directory **/var/db/config**, which is on the router's hard disk.

During rollback, the configuration you specify is loaded from the associated file. Only objects in the rollback configuration that differ from the previously loaded configuration are marked as changed (equivalent to `load update`).

Options

none	(Optional) Return to the most recently saved configuration.
number	(Optional) Configuration to return to. The range of values is from 0 through 49. The most recently saved configuration is number 0, and the oldest saved configuration is number 49. The default is 0.
rescue	(Optional) Return to the rescue configuration.
revision ***revision-string***	(Option) Use a configuration revision identifier to rollback to a specific configuration. Use the "show system commit include-configuration-revision" on page 26754 command to view the configuration revision identifier for each revision.

Required Privilege Level

rollback—To roll back to configurations other than the one most recently committed.

Release Information

Command introduced before Junos OS Release 7.4.

Option `revision` introduced in Junos OS Release 20.4R1 and Junos OS Evolved Release 20.4R1.

root-authentication

IN THIS SECTION

- Syntax | 15832
- Hierarchy Level | 15832
- Description | 15833
- Options | 15833
- Required Privilege Level | 15833
- Release Information | 15834

Syntax

```
root-authentication {
    encrypted-password "password";
    no-public-keys
    ssh-ecdsa name {
        from from;
    }
    ssh-ed25519 name {
        from from;
    }
    ssh-rsa name {
        from from;
    }
}
```

Hierarchy Level

```
[edit system]
```

Description

Configure the authentication methods for the root-level user, whose username is `root`.

You can use the `ssh-ecdsa`, `ssh-ed25519`, or `ssh-rsa` statements to directly configure SSH ECDSA, ED25519, or RSA keys to authenticate root logins. You can configure more than one public key for SSH authentication of root logins as well as for user accounts. When a user logs in as root, the public keys are referenced to determine whether the private key matches any of them.

> **NOTE**: There is a difference in the way a plain-text password is hashed and stored as encrypted in Junos OS release 15.1 and newer vs. that used in release 12.3 and earlier.
>
> In Junos OS release 12.3 and earlier images, encrypting and decrypting of passwords using SHA-256 is not supported. This is a limitation in Junos OS release 12.3. Therefore, if a password that is encrypted by using SHA-256 in Junos OS release 15.1 is provided to Junos OS releases 12.3 and earlier, the password decryption will fail.
>
> See this KB article for instructions on how to first configure a compatible MD5 hashed root password before you downgrade. If you downgrade without first configuring a compatible root password you will not be able to login as root after the downgrade.

Options

encrypted-password "*password*"	Specify the MD5 or other password. You can specify only one encrypted password. You cannot configure a blank password using blank quotation marks (" "). You must configure a password whose number of characters range from 1 through 128 characters and enclose the password in quotation marks.
no-public-keys	Disable SSH public key-based authentication.
ssh-ecdsa *name* from *from*	Use an SSH ECDSA public key. You can specify one or more public keys.
ssh-ed25519 *name* from *from*	Use an SSH ED25519 public key. You can specify one or more public keys.
ssh-rsa *name* from *from*	Use an SSH RSA public key. You can specify one or more public keys.

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

- Options | 15837
- Required Privilege Level | 15838
- Release Information | 15838

Syntax

```
root-login (allow | deny );
```

Hierarchy Level

```
[edit system services ssh]
```

Description

Control user access to the JDM through SSH.

Default

`root-login allow` is the default.

Options

`allow`—Allow users to log in to the JDM as root through SSH.

`deny`—Disable users from logging in to the JDM as root through SSH. This configuration option is applicable only to the JDM management interface (jmgmt0). Setting this configuration option does not block the internal JDM to JDM communication, which uses root account with password-less authentication method.

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

root-streaming

IN THIS SECTION

- Syntax | 15838
- Hierarchy Level | 15839
- Description | 15839
- Required Privilege Level | 15840
- Release Information | 15840

Syntax

```
root-streaming;
```

Hierarchy Level

```
[edit security log],
[edit logical-systems name security log],
[edit tenants name security log]
```

Description

The `root-streaming` option allows the user logical systems and tenant systems to generate the logs using the root system's stream configuration. If you configure `root-streaming` option under user logical systems and tenant systems in stream mode, all the logs of this user logical system and tenant systems will be sent out according to root logical and tenant system's configuration.

The `root-streaming` option works together with the stream mode. If user logical system is in event mode, the `root-streaming` option will not take effect. If user logical system is in stream mode and root logical systems is in event mode, the `root-streaming` option will try to get the streams in root but the logs will not be sent out. Table 1 provides a detailed behavior of user logical system logs.

Table 136: root-streaming option for root and logical systems in different mode

Logical systems mode	Root logical systems mode	Status of the root-streaming option for logical systems	Behavior of logical systems logs
Event mode		Enabled	Send to Routing Engine
Stream mode	Event mode	Enabled	Cannot send out
	Stream mode	Enabled	Send to root log server
	Stream-event mode	Enabled	Send to root log server
Stream-event mode	Event mode	Enabled	Send to Routing Engine
	Stream mode	Enabled	Send to Routing Engine and root log server

Table 136: root-streaming option for root and logical systems in different mode *(Continued)*

Logical systems mode	Root logical systems mode	Status of the root-streaming option for logical systems	Behavior of logical systems logs
	Stream-event mode	Enabled	Send to Routing Engine and root log server
Event mode		Not Enabled	Send to Routing Engine
Stream mode		Not Enabled	Send to logical systems log server
Stream-event mode		Not Enabled	Send to Routing Engine and logical systems log server

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 20.3R1.

root-address

IN THIS SECTION

- Syntax | 15841
- Hierarchy Level | 15841
- Description | 15841

- Release Information | 15841

Syntax

```
root-address root-address;
```

Hierarchy Level

```
[edit logical-systems name routing-instances name provider-tunnel ldp-p2mp],
[edit logical-systems name tenants name routing-instances name provider-tunnel ldp-p2mp],
[edit routing-instances name provider-tunnel ldp-p2mp],
[edit tenants name routing-instances name provider-tunnel ldp-p2mp]
```

Description

Configure the non-default loopback address for LDP point to multi-point provider tunnels.

NOTE: A maximum of 9000 ingress replication provider tunnels are supported with 3 root addresses.

A maximum of 3 VRFs can be mapped to 3 root addresses.

Release Information

Statement introduced in Junos OS Release 24.4R1.

route (Access)

IN THIS SECTION

- Syntax | 15842

- Hierarchy Level | 15842
- Description | 15842
- Options | 15842
- Required Privilege Level | 15843
- Release Information | 15843

Syntax

```
route prefix {
    metric route-cost;
    next-hop next-hop;
    preference route-distance;
    qualified-next-hop
    tag route-tag;
    tag2 route-tag2;
}
```

Hierarchy Level

```
[edit routing-options access]
[edit dynamic-profiles profile-name routing-instances $junos-routing-instance routing-options
access],
[edit dynamic-profiles profile-name routing-instances $junos-routing-instance routing-options
rib routing-table-name access],
[edit dynamic-profiles profile-name routing-options access],
[edit dynamic-profiles profile-name routing-options rib routing-table-name access]
```

Description

Dynamically configure the parameters for access routes.

Options

prefix—Either the specific route prefix that you want to assign to the access route or one of the following route prefix variables.

- For IPv4 access routes, use the variable, `$junos-framed-route-ip-address-prefix`. The route prefix variable is dynamically replaced with the value in Framed-Route RADIUS attribute [22].
- For IPv6 access routes, use the variable, `$junos-framed-route-ipv6-address-prefix`. The variable is dynamically replaced with the value in Framed-IPv6-Route RADIUS attribute [99]. When you use this variable, you must configure it at either of the following hierarchy levels:
  - `[edit dynamic-profiles` *`profile-name`* `routing-instances $junos-routing-instance routing-options rib $junos-ipv6-rib access]`
  - `[edit dynamic-profiles` *`profile-name`* `routing-options rib $junos-ipv6-rib access]`

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.5.

Support at the `[edit dynamic-profiles` *`profile-name`* `routing-instances $junos-routing-instance routing-options access]` and `[edit dynamic-profiles` *`profile-name`* `routing-instances $junos-routing-instance routing-options rib` *`routing-table-name`* `access]` hierarchy levels introduced in Junos OS Release 10.1.

- Hierarchy Level | 15847
- Description | 15847
- Default | 15848

Required Privilege Level | 15848
Release Information | 15848

Syntax

```
route-accounting;
```

Hierarchy Level

```
[edit forwarding-options family inet6]
```

Description

Enables the collection of transit IPv6 statistics at both the physical interface and logical interface levels on third-generation FPCs (FPC3-PTX-U2 and FPC3-PTX-U3 on PTX5000 and FPC3-SFF-PTX-U0 and FPC3-SFF-PTX-U1 on PTX3000), PTX1000, and PTX10008. Enable this statement prior to the route being created.

Egress accounting for IPv6 traffic is not performed for cases where MPLS packets arrive on a TCC interface and then egress the router as IPv6 packets.

PTX Series routers with first or second-generation FPCs do not display IPv6statistics for physical interfaces or logical interfaces. Transit statistics on child links in aggregated Ethernet interfaces are not included.

To view the IPv6 statistics for a given physical or logical interface, run the operational command, `show interfaces extensive interface | find IPv6` or `show interfaces statistics` *`interface-name`* `detail`. Note that the output displays packet and byte counts for transit traffic only. Locally generated packets are not included in the metrics.

NOTE:

- Enabling this option soon after disabling it on a third-generation FPCs (FPC3-PTX-U2 and FPC3-PTX-U3 on PTX5000 and FPC3-SFF-PTX-U0 and FPC3-SFF-PTX-U1 on

PTX3000), PTX1000, and PTX10008, restarts the accounting from zero and does not retain the statistics that was previously accounted.

- On third-generation FPCs in PTX series, egress accounting for IPV6 traffic is not performed for cases where MPLS packets arrives on TCC interface and egress out of the router as IPV6 packets.

Default

Disabled

Required Privilege Level

interface—To view this statement in the configuration.

- Release Information | 15849

Syntax

```
route-active-on (node0 | node1);
```

Hierarchy Level

```
[edit policy-options condition condition-name]
```

Description

In chassis cluster configurations, the incoming traffic from the core network is sent to the interface that exists on the current active node . For a route advertised by BGP, a policy is applied on BGP configuration before exporting routes. An additional term in the policy match condition determines the current active device (node) before making the routing decision. In this way, the traffic is processed by the active node.

Options

node0	Route active on node 0
node1	Route active on node 1

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

  export-action (allow | skip);
  import-action (allow | skip);
 }
 community {
  export-action (allow | skip);
  import-action (allow | skip);
 }
 preference {
  export-action (allow | skip);
  import-action (allow | skip);
 }
}
```

Hierarchy Level

```
[edit routing-instances name protocols evpn ip-prefix-routes]
```

Description

You can use the route-attributes import and export options to control which attributes to carry between the IP and EVPN routes. Use the export option when generating EVPN routes from IP routes and the import option when generating IP routes from EVPN routes.

Options

as-path

export-action

- allow — Inherit as-path from IP routes to EVPN routes.
- skip — Do not inherit as-path from IP routes to EVPN routes.

import-action

- allow — Inherit as-path from EVPN routes to IP routes.
- skip — Do not inherit as-path from EVPN routes to IP routes.

community

export-action

- allow — Inherit community from EVPN routes to IP routes.
- skip — Do not inherit community from EVPN routes to IP routes.

import-action

- allow — Inherit community from EVPN routes to IP routes.
- skip — Do not inherit community from EVPN routes to IP routes.

preference

export-action

- allow — Inherit preference from EVPN routes to IP routes.
- skip — Do not inherit preference from EVPN routes to IP routes.

import-action

- allow — Inherit preference from EVPN routes to IP routes.
- skip — Do not inherit preference from EVPN routes to IP routes.

Required Privilege Level

```

Description

Specify an identifier attached to a route that distinguishes to which VPN or virtual private LAN service (VPLS) the route belongs. Each routing instance must have a unique route distinguisher (RD) associated with it. The RD places bounds around a VPN so the device can use the same IP address prefixes in different VPNs without having the addresses overlap. You must configure the route-distinguisher statement for instances with instance type `vrf`.

Use the following guidelines when you assign RDs:

- For Layer 2 (L2) VPNs and VPLS, if you configure the `l2vpn-use-bgp-rules` statement, you must configure a unique RD for each PE router participating in the routing instance.

  If you configure mesh groups, the RD in each mesh group must also be unique.

- For Ethernet VPNs (EVPNs), you must configure a unique RD for each provider edge (PE) device participating in the routing instance to ensure that the prefixes generated by different PEs are unique.

- For other VPNs besides L2 VPNs, VPLS, and EVPNs, we recommend that you use a unique RD for each PE device participating in a particular routing instance. You can alternatively use the same RD on all PE devices for the same VPN routing instance, but if you use a unique RD, you can determine the customer edge (CE) router from which a route originated within the VPN.

- On EVPN data center interconnect (DCI) gateway devices, if you configure an interconnect RD at the `[edit routing-instances name protocols evpn interconnect]` hierarchy, the interconnect RD must be different from the local RD in the routing instance.

> **NOTE**: When you configure DCI with seamless stitching for EVPN Type 2 routes, the device throws a commit error if you try to configure the same value for the interconnect RD and the local RD.
>
> To enforce this condition for DCI seamless stitching with EVPN Type 5 routes as well, you also see a commit error with Junos OS and Junos OS Evolved Releases starting in 22.4R2 and 23.1R1.

CAUTION: We strongly recommend that if you change an RD that you configured and committed previously, or change the routing instance type from `virtual-router` to `vrf`, make either of those changes during a maintenance window, as follows:

1. Deactivate the routing instance.
2. Change the RD.
3. Activate the routing instance.

Options

as-number:*number*—*as-number* is an assigned AS number, and *number* is any 2-byte or 4-byte value. The AS number can be from 1 through 4,294,967,295. If the AS number is a 2-byte value, the administrative number is a 4-byte value. If the AS number is 4-byte value, the administrative number is a 2-byte value. An RD consisting of a 4-byte AS number and a 2-byte administrative number is defined as a type 2 RD in RFC 4364 *BGP/MPLS IP VPNs*.

NOTE: In Junos OS Release 9.1 and later, the numeric range for AS numbers is extended to provide BGP support for 4-byte AS numbers, as defined in RFC 4893, *BGP Support for Four-octet AS Number Space*. All releases of Junos OS support 2-byte AS numbers. To configure an RD that includes a 4-byte AS number, append the letter "L" to the end of the AS number. For example, an RD with the 4-byte AS number 7,765,000 and an administrative number of 1,000 is represented as `77765000L:1000`.

In Junos OS Release 9.2 and later, you can also configure a 4-byte AS number using the AS dot notation format of two integer values joined by a period: <*16-bit high-order value in decimal*>.<*16-bit low-order value in decimal*>. For example, the 4-byte AS number of 65,546 in the plain-number format is represented as 1.10 in AS dot notation format.

number:*id*—Number and identifer expressed in one of these formats: *16-bit number*.*32-bit identifier* or *32-bit number*.*16-bit identifier*.

ip-address:*id*—IP address (*ip-address* is a 4-byte value) within your assigned prefix range and a 2-byte value for the *id*. The IP address can be any globally unique unicast address.

- **Range:** 0 through 4,294,967,295 (2^{32} – 1). If the router you are configuring is a BGP peer of a router that does not support 4-byte AS numbers, you need to configure a local AS number. For more information, see *Using 4-Byte Autonomous System Numbers in BGP Networks Technology Overview*.

> **NOTE**: For Ethernet VPNs (EVPNs), an RD that includes zero as the *id* value is reserved for the default EVPN routing instance by default. Because you can't assign the same RD for two routing instances, the device throws a commit error if you use an RD of the form *ip-address*:*id* with *id* value zero for another routing instance.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Support at `[edit routing-instances routing-instance-name protocols vpls mesh-group mesh-group-name]` hierarchy level introduced in Junos OS Release 11.2.

Support at `[edit routing-instances routing-instance-name protocols l2vpn mesh-group mesh-group-name]` hierarchy level introduced in Junos OS Release 13.2.

Support at the following hierarchy levels introduced in Junos OS Release 20.3R1 on QFX Series switches: `[edit protocols evpn interconnect]` and `[edit routing-instances routing-instance-name protocols evpn interconnect]`.

route-distinguisher-id

IN THIS SECTION

- Syntax | 15860
- Hierarchy Level | 15860
- Description | 15860
- Options | 15861
- Required Privilege Level | 15861
- Release Information | 15861

Syntax

```
route-distinguisher-id ip-address;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options],
[edit routing-options]
```

Description

The automatic Route-Distinguisher feature uses the `route-distinguisher-id` command to create a Type 1 Route-Distinguisher to the routing instance, based on RFC 4364, BGP/MPLS IP Virtual Private Networks (VPNs).

The 4-octet `Administrator` subfield of the Route-Distinguisher uses the IP address that is configured as the `route-distinguisher-id`, which is common for all routing instances in the local system. Additionally, the system assigns an autogenerated 2-octet number as the `Assigned Number` subfield that is unique per the routing instances.

If you configure the `route-distinguisher` statement in addition to the `route-distinguisher-id` statement, the value configured for `route-distinguisher` supersedes the value generated from `route-distinguisher-id`.

> **NOTE**: To avoid a conflict between the configured and auto-generated route distinguisher values, you must ensure that the first half (IP address) of the `route-distinguisher` obtained by configuring the `route-distinguisher` statement is different from the IP-address configured in the `route-distinguisher-id` statement.

Options

`ip-address`—Address for routing instance.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

route-filter

IN THIS SECTION

- Syntax | 15862
- Hierarchy Level | 15862
- Description | 15862
- Default | 15862
- Required Privilege Level | 15862

Release Information | 15862

Syntax

```
route-filter (no-walkup | walkup);
```

Hierarchy Level

```
[edit logical-systems logical-system-name policy-options defaults],
[edit logical-systems logical-system-name policy-options policy-statement policy-statement-name
defaults],
[edit policy-options defaults],
[edit policy-options policy-statement policy-statement-name defaults]
```

Description

Enable or disable walkup globally or locally for route filters in a particular policy statement or globally. The walkup feature examines more than the longest match route filters in a policy statement term with more than one route filter, allowing consolidation of terms and a potential performance enhancement.

Default

By default, no route filter walkup is performed.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 13.3.

- Release Information | 15867

route-filter-list

```
route-filter-list route-filter-list-name {
ip-addresses <exact | longer | orlonger | prefix-length-range | through | upto> label range
start : end;
ip-addresses <exact | longer | orlonger | prefix-length-range | through | upto> label-allocation-
fallback-reject;
ip-addresses exact label value;
ip-addresses exact label-allocation-fallback-reject;
```

Hierarchy Level

```
[edit logical-systems logical-system-name policy-options],
[edit policy-options]
```

route-filter-list (usage)

```
route-filter-list route-filter-list-name;
```

Hierarchy Level

```
[edit logical-systems logical-system-name policy-statement policy-statement-name term term-name
from],
[edit policy-options policy-statement policy-statement-name term term-name from]
```

Description

The route filter list is a user-configured list of individual route filters that you create at the `[edit policy-options]` hierarchy level. Each item in the list consists of a complete route filter statement, made up of a destination prefix, a match type, and an optional action. You can re-use the list in different policies, adding whatever qualifiers you need, rather than having to re-create it for every different case, as shown in the examples below.

```
[edit]
user@router# show policy-options route-filter-list rf-test-list
203.0.113.0/24 address-mask 255.255.255.0;
192.0.2.0/26 orlonger reject;
198.51.100.8/29 exact accept;
```

Once configured, the `route-filter-list` is used by referencing its *`route-filter-list-name`* in a `policy-statement` at the `[edit policy-options policy-statement` *`policy-statement-name`* `term` *`term-name`* `from]` hierarchy level. Route filter lists can be used in conjunction with other `route-filter` statements.

For example:

```
[edit]
user@router# show policy-options policy-statement test-route-filter-list-statement
from {
    route-filter 198.51.100.32/29 exact accept;
    route-filter 192.0.2.1/32 exact;
    route-filter-list rf-test-list;
}
then reject;
```

If one action is associated with the `route-filter-list` entry and another action is associated with the list-level entry, the action associated with the list-level entry takes precedence.

```
policy-options {
    route-filter-list RFL-1 {
        198.1.1.0/24 exact;
        198.2.1.0/24 orlonger;
    }
    route-filter-list RFL-2 {
        198.1.1.0/24 exact reject;
        198.2.1.0/24 orlonger accept;
    }
    policy-statement pol {
        term 1 {
            from {
                route-filter-list RFL-1 longer accept;
            }
        }
        term 2 {
            from {
                route-filter-list RFL-2 longer reject;
            }
        }
    }
}
```

Here is an example on how to specify policy-based control for BGP-LU labels being allocated for a given prefix:

```
[edit]
user@host# show policy-options route-filter-list rfl-1{
198.51.1.1/32 exact {
    label 1000101;
    next-hop 198.52.1.2;
    accept;
    label-allocation-fallback-reject;
}
198.51.1.0/24 prefix-length-range /24-/32 {
    label range 1000000:1000200;
    next-hop 198.53.2.2;
    accept;
}
}
```

```
[edit]
user@host# show policy-options policy-statement p-1{
from {
    route-filter-list rfl-1;
}
then accept;
}
```

```
[edit]
user@host# show protocols bgp group ibgp{
type internal;
local-address 198.0.23.3;
family inet {
    labeled-unicast {
        per-prefix-label;
        }
    }
neighbor 198.0.12.1 {
    export p-1;
}
}
```

Options

When specifying a match prefix, you can specify an exact match with a particular route or a less precise match. You can configure either a common action that applies to the entire list or an action associated with each prefix.

- *list-name*—Name of route-filter-list of routes to match.
- *exact*—Exactly match the prefix length.
- *longer*—Mask is greater than the prefix length.
- *orlonger*—Mask is greater than or equal to the prefix length.
- *prefix-length-range*—Mask falls between two prefix lengths.
- *upto*—Mask falls between two prefix length.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 16.1.

Support on PTX1000, PTX10000, and PTX10003 Packet Transport Routers introduced in Junos OS Release 20.2R1 for the following list-level qualifiers: `exact`, `longer`, `orlonger`, `prefix-length-range`, and `upto`.

[edit logical-systems logical-system-name interfaces interface-name unit logical-unit-number family inet address address vrrp-group group-id track],
[edit logical-systems logical-system-name  interfaces interface-name unit logical-unit-number family inet6 address address vrrp-inet6-group group-id track]
```

Description

Enable route tracking for a Virtual Router Redundancy Protocol (VRRP) group.

Options

prefix—Route to be tracked for this VRRP group.

priority-cost ***priority***—The value subtracted from the configured VRRP priority when the tracked interface or route is down, forcing a new primary router election. The sum of all the costs for all interfaces or routes that are tracked must be less than or equal to the configured priority of the VRRP group.

routing-instance ***instance-name***—Routing instance in which the route is to be tracked. If the route is in the default, or global, routing instance, the value for ***instance-name*** must be **default**.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

- Release Information | 15874

Syntax

```
route-monitoring {
    none;
    loc-rib;
    post-policy {
        exclude-non-eligible;
    }
    pre-policy {
        exclude-non-feasible;
    }
    rib-out {
        post-policy;
        pre-policy;
    }
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols bgp bmp],
[edit logical-systems logical-system-name protocols bgp group group-name bmp],
[edit logical-systems logical-system-name protocols bgp group group-name neighbor address bmp],
[edit logical-systems logical-system-name routing-options bmp],
[edit logical-systems logical-system-name routing-options bmp station station-name],
```

```
[edit protocols bgp bmp],
[edit protocols bgp group group-name bmp],
[edit protocols bgp group group-name neighbor address bmp],
[edit routing-options bmp],
[edit routing-options bmp station station-name]
```

Description

Specify whether BMP should send pre-policy route monitoring messages, post-policy route monitoring messages, both types of messages, or none at all. The pre-policy can be configured to exclude routes that are non-feasible for the decision process (for example, a route loop). The post-policy can be configured to exclude routes that are not eligible for the decision process (for example, protocol next-hop not resolved).

You can also selectively enable or disable BMP route monitoring at various hierarchy levels (for example, `[edit protocols bgp group group-name]` or `[edit protocols bgp group group-name neighbor address]`).

> **NOTE**: If you have initially configured pre-policy route monitoring, but later delete the initial configuration and configure post-policy route monitoring, then the previously advertised pre-policy routes are withdrawn. Conversely, if you have initially configured post-policy route monitoring and later modify it to pre-policy route monitoring, then the previously advertised post-policy routes are withdrawn.

Options

none Explicitly disables BMP route monitoring.

- **Default:** If you configure the `route-monitoring` statement at the `[edit routing-options bmp]` hierarchy level, the default option is `pre-policy`.

> **NOTE**: If `post-policy` or `pre-policy` is not configured explicitly, then the default mode `pre-policy` would be applicable.
>
> The `route-monitoring` options `pre-policy`, `post-policy`, `rib-out pre-policy`, and `rib-out post-policy` are not mutually exclusive. You can configure any combination, or none, or all. If none of the options are configured, `pre-policy` remains as the default.

If you configure the `route-monitoring` statement at any of the `[edit protocols bgp]` hierarchy levels, the default option is to inherit the configuration from the `route-monitoring` statement configured at the `[edit routing-options bmp]` hierarchy level.

loc-rib Send local-rib route monitoring messages.

post-policy For BMP route monitoring, allows you to exclude routes that are non-eligible for the decision process (for example, protocol next-hop not resolved). This represents the view of the BGP routes after running the import policy. If the import policy has rejected the BGP route, the route does not exist in the post policy view.

> **NOTE**: If post-policy is configured, the device applies the import policies on the routes received so that BMP can display the routes as follows:
>
> - If an import policy modifies any parameters in the route, the route is displayed by BMP with the new values.
> - If an import policy modifies the next-hop and the next-hop is unresolved by the local device, the route is displayed by BMP as reachable.
> - If an import policy rejects a route, it is displayed as unreachable in the BMP update.
> - If a route is received with an unreachable next-hop, but the import policy doesn't reject the route, then BMP displays the route as reachable.

- **Values:** exclude-non-eligible—Exclude routes that are non-eligible from the decision process.

  Using post-policy with the exclude-non-eligible option causes an unreachable BMP update in the following cases:

  - If an import policy modifies the next-hop and the next-hop is unresolved by the local router, the route is displayed by BMP as unreachable.
  - if a route is received with a next-hop that is unreachable and the import policy does not reject this route, it is displayed by BMP as unreachable.

pre-policy Excludes routes that are non-feasible from the BMP route monitoring decision process (for example, a route loop). This represents the view of the BGP routes before running the import policy.

- **Values:** exclude-non-feasible—Exclude routes that are non-feasible from the decision process.

rib-out Send adj-ribs-out route monitoring messages.

- Values:
  - post-policy—Send post-policy adj-ribs-out route monitoring messages.
  - pre-policy—Send pre-policy adj-ribs-out route monitoring messages.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 13.2X51-D15.

`rib-out` option introduced in Junos OS Release 19.1R1.

- Release Information | 15875

Syntax

```
route-record;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options],
[edit routing-options]
```

Description

Export the AS path and routing information to the traffic sampling process.

Before you can perform flow aggregation, the routing protocol process must export the AS path and routing information to the sampling process.

> **NOTE**: Starting with Junos OS Release 15.1, when you commit a minor configuration change, the routing protocol process sends only AS paths that are active routes to the FPCs. Not all known AS paths are sent to the FPC, thereby considerably reducing the memory and CPU usage, resulting in a faster route record database update.

Required Privilege Level

routing—To view this statement in the configuration.

[edit system services dhcp-local-server dhcpv6],
[edit system services dhcp-local-server group group-name],
[edit system services dhcp-local-server dhcpv6 group group-name]
```

Description

Configure the jdhcpd process to suppress the installation of access, access-internal, or destination routes during client binding.

NOTE: You cannot suppress access-internal routes when the subscriber is configured with both IA_NA and IA_PD addresses over IP demux interfaces—the IA_PD route relies on the IA_NA route for next hop connectivity.

Options

access (DHCPv6 only) Suppress installation of access routes. You can use the `access` and `access-internal` options in the same statement for DHCPv6.

access-internal In a DHCPv4 hierarchy, suppress installation of both access-internal and destination routes. In a DHCPv6 hierarchy, suppress access-internal routes only. Can be configured in the same statement with the `access` option.

destination (DHCPv4 only) Suppress installation of destination routes. This option and the `access-internal` option are mutually exclusive; however, the `access-internal` option also suppresses destination routes.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 13.2.

Syntax

```
route-target-filter destination {
    group group-name;
    local;
    neighbor address;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options rib bgp.rtarget.0 static],
[edit routing-options rib bgp.rtarget.0 static]
```

Description

Statically configure route target filtering. Route target filtering allows you to distribute VPN routes to only the routers that need them. In VPN networks without route target filtering configured, BGP distributes all static VPN routes to all of the VPN peer routers. You can add static routes to the bgp.rtarget.0 routing table with specific NLRI-imposed constraints.

Options

destination Allows you to specify the static route destination. This value must be in the format x:y/len. The x value is either an IP address or an AS number followed by an optional L to indicate a 4 byte AS number, and y is a number (for example, 123456L:100/64).

group *group-name(s)* Installs an RT-Constrain filter for the destination for all peers in the specified BGP group. The route and corresponding BGP group are displayed in the output of the `show bgp group rtf detail` command.

local Causes the router to originate the route target constrain NLRI, but does not install any filtering state for the prefix. This behavior can be useful when the router should always

receive VPN routes with this route-target regardless of the state of a given BGP peering session or group status. The route is not displayed in the output of the `show bgp group rtf detail` command unless it is also included in either the BGP neighbor or BGP group configuration.

neighbor *address*

Installs an RT-Constrain filter for the destination for this BGP neighbor. The route is displayed in the output of the `show bgp group rtf detail` command. Specify the BGP neighbor using the router's IP address.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.2.

Description

Configure router advertisement to multicast router's availability. Router advertisement announces the address autoconfiguration and discovers the link local addresses of the neighboring routers. The router discovery messages enables the host to discover the existence of neighboring routers. Router advertisment messages contain prefixes that are used for address autoconfiguration.

Options

accept-current-hop-limit-max

(Optional) Current hop limit acceptable maximum for incoming RA.

- **Range:** 1 through 255 units.

accept-current-hop-limit-min

(Optional) Current hop limit acceptable minimum for incoming RA.

- **Range:** 1 through 255 units.

accept-reachable-time-max

(Optional) Reachable time acceptable maximum for incoming RA.

- **Range:** 1000 through 3600000 milliseconds.

accept-reachable-time-min

(Optional) Reachable time acceptable minimum for incoming RA.

- **Range:** 1000 through 3600000 milliseconds.

accept-retransmit-time-max

(Optional) Retransmit Time acceptable maximum for incoming RA.

- **Range:** 1000 through 3600000 milliseconds.

accept-retransmit-time-min

(Optional) Retransmit Time acceptable min for incoming RA (1000..3600000 milliseconds).

- **Range:** 1000 through 3600000 milliseconds.

autonomus

(Optional) Indicates the value to be placed in the autonomous flag field in the prefix information option. The "autonomous address-configuration flag", indicates if the option applies to the stateless autoconfiguration.

no-autonomus	(Optional) Indicates to silently ignore the prefix information option as stateless autoconfiguration is not applicable.
current-hop-limit	(Optional) Current hop limit is the default value placed in the hop count field of the IP header for outgoing packets. • **Range:** 0 through 255.
default-lifetime	(Optional) Router lifetime is the lifetime associated with a default router. • **Range:** 0 through 9000 seconds.
dns-search-list	(Optional) DNS search list configuration.
dns-server-address	(Optional) Recursive DNS address configuration.
downstream	(Optional) Used to configure the list of downstream interfaces a given upstream interface.
downstream-mode	(Optional) Used for the interface as downstream interface for RA proxy.
file	(Optional) Trace file options.
flag	(Optional) Tracing parameters.
link-mtu	(Optional) Link MTU. Include the maximum transmission unit (MTU).
no-link-mtu	(Optional) Don't link MTU. Does not include the maximum transmission unit (MTU).
managed-configuration	(Optional) Set managed address configuration. Enable host to use stateful autoconfiguration.
no-managed-configuration	(Optional) Don't set managed address configuration. Disable host from using stateful autoconfiguration.
max-advertisement-interval	(Optional) Maximum advertisement interval. Set the maximum interval between each router advertisement message. • **Range:** 4 through 1800 seconds.
min-advertisement-interval*seconds*	(Optional) Minimum advertisement interval. Set the minimum interval between each router advertisement message. • **Range:** 3 through 1350 seconds.

other-stateful-configuration	(Optional) Set other stateful configuration. Enable autoconfiguration of other nonaddress-related information.
no-other-stateful-configuration	(Optional) Don't set other stateful configuration. Disable autoconfiguration of other nonaddress-related information.
parameter-preference	(Optional) Used for RA proxy. The TLVs/options from RA packet will be proxied if parameter-preference is set as “proxied”. If parameter-preference is set as “configured”, configured options will have preference and configured options will be sent in the RA packet.
passive-mode	(Optional) RA receive only mode.
preference	(Optional) Set the preference for router selection.
prefix	(Optional) Specifies the prefixes that are on-link and/or are advertised for stateless-address autoconfiguration.
nat-prefix	(Optional) Used to configure NAT prefix to be advertised in the RA packet.
preferred-lifetime	(Optional) Indicates the length of time in seconds (relative to the time the packet is sent) for which addresses are generated from the prefix via stateless address autoconfiguration remain preferred.
reachable-time	(Optional) Reachable time. Set the length of time that a node considers a neighbor reachable until another reachability confirmation is received from that neighbor. • **Range:** 0 through 3600000 milliseconds
retransmit-timer*seconds*	(Optional) Retransmit timer. Set the retransmission frequency of neighbor solicitation messages. • 0 through 4294967295 milliseconds.
rio-prefix	(Optional) Route information option configuration.
rio-lifetime	(Optional) Time in seconds for which the advertised route information in the route information option is valid.
rio-preference	(Optional) High, Low, or Medium preference value indicates whether to prefer the advertised route information in the route information option over other default routes.
solicit-router-advertisement-unicast	(Optional) Enable solicited router advertisement as unicast.

upstream-mode (Optional) Used for RA proxy, when enabled for upstream interface. The packets received on the upstream interface will be proxied to one or more downstream interfaces.

valid-lifetime (Optional) Indicates the length of time in seconds (relative to the time the packet is sent) for which the prefix is valid for the purpose of on-link determination.

virtual-router-only (Optional) Send advertisements only for vrrp-inet6-group.

- **Range:** 0 through 3600000 milliseconds

        }
    }
}
```

Hierarchy Level

```
[edit forwarding-options access-security]
```

Description

Configure IPv6 Router Advertisement (RA) guard. In an IPv6 deployment, RA guard protects against rogue RA messages generated either maliciously or unintentionally by unauthorized or improperly configured routers connecting to the network segment. An RA guard policy is used to validate incoming RA messages on the basis of whether they match the conditions defined in a policy. The policy can be either an accept policy or a discard policy. When RA guard is enabled by using an accept policy, any RA messages that match the conditions defined in the policy are forwarded, and RA messages that do not match the conditions are dropped. When RA guard is enabled by using a discard policy, any RA messages that match the conditions are dropped, and RA messages that do not match the conditions are forwarded.

You can enable RA guard on an interface or on a VLAN. You must first configure a policy at the [`edit forwarding-options access-security router-advertisement-guard`] hierarchy level. The policy is then applied to an

interface at the [`edit forwarding-options access-security router-advertisement-guard interface` *`interface-name`*] hierarchy level, or to a VLAN at the [`edit forwarding-options access-security router-advertisement-guard vlan` *`vlan-name`*] hierarchy level.

> **NOTE**: If you apply an RA guard policy on an interface, you must enable RA guard on the VLAN that is associated with that interface using the `vlan` statement at the [`edit forwarding-options access-security router-advertisement-guard`] hierarchy level.

You can configure RA guard to be stateless or stateful. Stateless RA guard enables a switch to examine incoming RA messages and filter each message on the basis of whether it matches the conditions configured in the policy. For example, an interface can be statically configured to forward RA messages only from predefined sources. Stateful RA guard enables a switch to learn about legitimate senders of RA messages and store this information, which is used to validate senders of subsequent RA messages. For example, an interface that is in the learning state and receives RA messages from legitimate senders dynamically transitions to the forwarding state, in which RA messages from valid senders are forwarded to their destination.

The remaining statements are explained separately. See CLI Explorer.

[edit logical-systems logical-system-name routing-instances routing-instance-name routing-
options],
[edit logical-systems logical-system-name routing-options],
[edit routing-instances routing-instance-name routing-options],
[edit routing-options]
```

Description

Specify the routing device's IP address.

The router identifier is used by BGP and OSPF to identify the routing device from which a packet originated. The router identifier usually is the IP address of the local routing device. If you do not configure a router identifier, the IP address of the first interface to come online is used. This is usually the loopback interface. Otherwise, the first hardware interface with an IP address is used.

> **NOTE**: We strongly recommend that you configure the router identifier under the `[edit routing-options]` hierarchy level to avoid unpredictable behavior if the interface address on a loopback interface changes.

You must configure a router-id in order for BGP and OSPF to function in a routing instance. Use the **show route instance detail** command to display the router-id value for a routing instance. If the router-id is `0.0.0.0`, then the routing instance has no router-id.

For more information about the router identifier in OSPF, see *Example: Configuring an OSPF Router Identifier*.

> **NOTE**: If you run OSPF3 or IPv6 based BGP peering in a routing instance, you must configure a router identifier (`router-id`) in the routing instance itself. In other words, the `router-id` used for the main routing instance is **not** inherited by other routing instances. Even if you run *only* OSPF3 or IPv6 BGP peering in a routing instance, a 32-bit `router-id` must be configured in the instance. This is because IPv6 routing protocols use the `router-id` for handshaking. **The router ID must be configured as a 4 octet (32 bit) unsigned non-zero integer value.**
>
> **It's often convenient to use an IPv4 address as the router ID. However, a valid IPv4 address is not required. The RID does not have to be a routable IPv4 address. You can configure any 32-bit value that is unique within the routing domain.** If you do not configure the `router-id` in an IPv6 OSPF or BGP routing instance the IPv6 protocols will use an invalid value for the router ID (`0.0.0.0`) and the adjacency and connections will fail

When you configure a router ID with an IP address that differs from the BGP local address for EVPN routing instances, you must also configure a policy that exports the local IP address for BGP routes. This ensures that EVPN traffic will be properly routed. For more information on exporting BGP routes, see *Basic BGP Routing Policies*.

Options

address—IP address of the routing device.

- **Default:** Address of the first interface encountered by Junos OS

Starting in Junos OS Release 20.4R1, you can establish a BGP connection with the BGP identifier that is a 4-octet, unsigned, and non-zero integer and it needs to be unique only within the Autonomous System (AS) per *RFC6286, Autonomous-System-Wide Unique BGP Identifier for BGP-4*

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

routing-engine

IN THIS SECTION

- Syntax | 15904
- Hierarchy Level | 15905
- Description | 15905
- Required Privilege Level | 15905
- Release Information | 15905

Syntax

```
routing-engine {
    on-disk-failure {
        disk-failure-action (halt | reboot);
    }
}
```

Hierarchy Level

```
[edit chassis]
[edit chassis interconnect-device name],
[edit chassis node-group name]
```

Description

Configure a Routing Engine to halt or reboot automatically when a hard disk error occurs. A hard disk error may cause a Routing Engine to enter a state in which it responds to local pings and interfaces remain up, but no other processes are responding. Rebooting or halting prevents this.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.1.

routing-engine (Chassis)

IN THIS SECTION

- Syntax | 15906
- Hierarchy Level | 15906
- Description | 15906

- Options | 15907
- Required Privilege Level | 15907
- Release Information | 15907

Syntax

```
routing-engine {
    on-disk-failure (Chassis Routing Engine)
    {
        disk-failure-action (halt | reboot);
    }
    disk {
        ssd-series ssd-series-name {
            id id-num {
                id-threshold id-threshold-value;
                id-value (norm | raw);
                id-flag (high | low);
            }
        }
        smart-check{
    }
}
```

Hierarchy Level

```
[edit chassis]
```

Description

Configure a Routing Engine to halt or reboot automatically when a hard disk error occurs. A hard disk error may cause a Routing Engine to enter a state in which it responds to local pings and interfaces remain up, but no other processes are responding. Rebooting or halting prevents this. You can also configure the device to perform certain health checks on the Routing Engine solid-state drive (SSD) and log a health event or raise an alarm in case a predefined health attribute threshold is breached.

Options

disk Configure health check parameters for the SSD.

ssd-series *ssd-series-name* Specify the SSD series name.

id *id-num* Specify the ID of the SSD smart attribute for which you are configuring the health check. You can view the smart attributes and their IDs of an SSD by using the command `show vmhost hard-disk-test status disk /dev/sda`.

- **Range:** 1 - 255

id-threshold Specify the SSD smart attribute threshold, breaching which will result in the device logging a health event or raising an alarm.

id-value Choose the attribute value type from the following options:

- norm—Use this option to instruct the device to consider normalized value for the specified smart attribute.
- raw—Use this option to instruct the device to consider raw value for the specified smart attribute.

id-flag Choose the attribute value flag from the following options:

- high—The software considers the threshold to be breached if the value is greater than smart threshold.
- low—The software considers the threshold to be breached if the value is less than smart threshold.

smart-check Configure the device to raise alarm when an error occurs. See "smart-check" on page 28045.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

The `disk-failure-action` statement added in Junos OS Release 9.0.

routing-engine (Chassis Redundancy)

IN THIS SECTION

- Syntax | 15908
- Hierarchy Level | 15908
- Description | 15908
- Default | 15908
- Options | 15909
- Required Privilege Level | 15909
- Release Information | 15909

Syntax

```
routing-engine slot-number (backup | disabled | master);
```

Hierarchy Level

```
[edit chassis redundancy]
```

Description

Configure Routing Engine redundancy.

Default

By default, the Routing Engine in slot 0 is the primary Routing Engine and the Routing Engine in slot 1 is the backup Routing Engine.

Options

slot-number—Specify the slot number (0 or 1).

Set the function of the Routing Engine for the specified slot:

- **master**—Routing Engine in the specified slot is the primary.
- **backup**—Routing Engine in the specified slot is the backup.
- **disabled**—Routing Engine in the specified slot is disabled.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

- Hierarchy Level | 15910
- Description | 15910
- Options | 15910
- Required Privilege Level | 15910
- Release Information | 15911

Syntax

```
routing-engine-profile profile-name {
    fields {
        field-name;
    }
    file filename;
    interval minutes;
    start-time time;
}
```

Hierarchy Level

```
[edit accounting-options]
```

Description

Create a Routing Engine profile to collect selected Routing Engine statistics and write them to a file in the `/var/log` directory.

Options

profile-name Name of the Routing Engine statistics profile.

start-time *time* (Optional) Specify the start time in *yyyy-mm-dd.hh:mm* local time format for the accounting profile. Sometimes, if the time at which the records are written to the accounting file is beyond the transfer interval window of the file, drifting of accounting records occurs. To prevent drifting and to have predictable timestamps of when accounting data is written to an accounting file, we can specify the start time option for the accounting profile.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

routing-engine (SNMP Resource Level)

IN THIS SECTION

- Syntax | 15913
- Hierarchy Level | 15913
- Description | 15913
- Options | 15913
- Required Privilege Level | 15914
- Release Information | 15914

Syntax

```
routing-engine  {
    resource <cpu | memory | open-files-count | process-count  | storage | temperature |
traceoptions > ;
    {
        interval <interval in secs>;
        moderate-threshold <percentage level>;
        high-threshold <percentage level>;
        critical-threshold <percentage level>;
        action <monitor | prevent | recover>;
    }
}
```

Hierarchy Level

```
[edit snmp health-monitor routing-engine]
```

Description

Override the global configuration for a resource.

Options

- `interval`—Monitoring interval in seconds.

  Range: 1 through 604800 seconds

  Default: 300 seconds

- `moderate-threshold`—Percentage of moderate threshold level resource utilization.

  Range: 30 through 99 percent

  Default: 70 percent

- `high-threshold` —Percentage of high-threshold level resource utilization.

  Range: 30 through 99 percent

  Default: 80 percent

- `critical-threshold` —Percentage of critical threshold level resource utilization.

  Range: 30 through 99 percent

  Default: 90 percent

- `action`–Enable action for all resources.

  Default: If action is not enabled, the default action is prevent.

> **WARNING**: If the system health management action for an affected resource is configured to recover, then certain instrusive operations necessary for preventing system breakdown are taken. Instrusive operations can include restarting or terminating processes, deleting files, and so on. Such action information is logged in the system health management history and system log.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

routing-header

IN THIS SECTION

- Syntax | 15915
- Hierarchy Level | 15915
- Description | 15915
- Required Privilege Level | 15915
- Release Information | 15915

Syntax

```
routing-header {
    header-type {
        match (equal | greater-than | less-than | not-equal);
        value header-value;
    }
}
```

Hierarchy Level

```
[edit  set security idp custom-attack attack-name attack-type signature protocol ipv6 extension-
header]
```

Description

Specify the IPv6 routing header type. The `routing-header` option inspects the routing-header type field and reports a custom attack if a match with the specified value is found. The `routing-header` option supports the following routing header types: `routing-header-type0`, `routing-header-type1`, and so on.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.3X48-D30.

routing-instance (Services)

IN THIS SECTION

Syntax | 15916

- Hierarchy Level | 15916
- Description | 15916
- Options | 15917
- Required Privilege Level | 15917
- Release Information | 15917

Syntax

```
routing-instance routing-instance-name{
    family inet {
        address ip-address;
    }
}
```

Hierarchy Level

```
[edit services app-engine compute-cluster compute-cluster-name local-management],
[edit services app-engine virtual-machines instance instance-name local-management]
```

Description

(Optional) Configure a routing instance for the JunosV App Engine infrastructure. Packets are restricted to the specified routing instance. By specifying the routing instance, the JunosV App Engine infrastructure can be made to operate in a non-default routing instance. This feature ensures that JunosV App Engine traffic can be segregated from other traffic.

If the `routing-instance` statement is absent from the `[edit services app-engine virtual-machines instance instance-name local-management]` hierarchy level, the virtual machine (VM) will inherit this routing instance from its `[edit services app-engine compute-cluster compute-cluster-name local-management]` hierarchy level.

NOTE: Additional configuration under the `[edit routing-instances]` hierarchy level is required to ensure that the Routing Engine interface address belongs to that particular routing instance on the routing engine. Each routing instance consists of sets of the

following: Routing tables, interfaces that belong to these routing tables (optional, depending upon the routing instance type), and routing option configurations.

Options

routing-instance-name	Name of the routing instance.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 13.2.

routing-instance (SNMPv3)

IN THIS SECTION

- Syntax | 15917
- Hierarchy Level | 15918
- Description | 15918
- Options | 15918
- Required Privilege Level | 15918
- Release Information | 15918

Syntax

```
routing-instance routing-instance-name;
```

Hierarchy Level

```
[edit snmp v3 target-address target-address-name]
```

Description

Specify a routing instance for an SNMPv3 trap target.

Options

routing-instance-name—Name of the routing instance.

To configure a routing instance within a logical system, specify the logical system name followed by the routing instance name. Use a slash (/) to separate the two names (for example, `test-ls/test-ri`). To configure the default routing instance on a logical system, specify the logical system name followed by `default` (for example, `test-ls/default`).

Required Privilege Level

snmp—To view this statement in the configuration.

snmp-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.3.

routing-instance (SNMP)

IN THIS SECTION

routing-instance (Advanced Policy-Based Routing)

IN THIS SECTION

- Syntax | 15928
- Hierarchy Level | 15928
- Description | 15928
- Options | 15929
- Required Privilege Level | 15929

Syntax

```
routing-instance name ;
```

Hierarchy Level

[edit security advance-policy-based-routing profile *profile-name* rule *rule-name* then]

Description

Specify a specific routing instance to which the device sends the matched packets.

When traffic arrives at the specified zone or interface, it is matched by the advanced policy-based routing (APBR) profile (application profile). The application profile matches applications and application groups and if the matching rule is found, the packets are routed to the routing instance that sends the traffic to a different interface as specified in the next-hop IP address.

The routing instances specify the routing table and the destination to which a packet is forwarded. The following types of routing instances are supported:

- Forwarding—Use this routing instance type for filter-based forwarding applications.
- Virtual router—Similar to the forwarding instance type, but used for non-VPN-related applications.

Options

name Specify the name of the routing instance.

Required Privilege Level

services—To view this statement in the configuration.

services-control—To add this statement to the configuration.

Configure the routing instance you want to use to update Automation scripts. To use a management instance, configure the `management-instance` statement along with the `routing-instance` statement, thus enabling JET scripts to use the non-default management routing instance mgmt_junos when refreshing the scripts.

Options

routing-instance-name Name of the routing instance. For the management instance, use `mgmt_junos`. Otherwise, you can specify any routing instance name.

> **NOTE**: You must also define the routing instance under the `[edit routing-instances]` hierarchy level.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 18.1R1.

Management Interface in a Non-Default Instance

routing-instance (Junos Telemetry Interface)

IN THIS SECTION

- Syntax | 15937
- Hierarchy Level | 15937
- Description | 15937
- Options | 15938
- Required Privilege Level | 15938
- Release Information | 15938

Syntax

```
routing-instance routing-instance-name;
```

Hierarchy Level

```
[edit services analytics export-profile export-profile-name]
```

Description

For legacy gRPC dialout connections, configure a routing instance in an export profile. You can only configure the routing instance in an export profile for legacy remote procedure call (gRPC) dial-out connections. An error is returned if the routing instance configured is used with User Datagram Protocol (UDP) transport.

Configuring the routing instance in an export profile is not mandatory. If you choose not to configure a routing instance, the default routing instance is applied.

Options

routing-instance A routing instance to be used for gRPC transport.

Required Privilege Level

Edit

Syntax

```
routing-instance-list {
    instance-name {
        port number;
    }
}
```

Hierarchy Level

```
[edit services rpm twamp server]
```

Description

Configure the Two-Way Active Measurement Protocol (TWAMP) servers on specific routing instances, instead of associating the TWAMP server at the system-level to apply to all routing instances configured on a router. The default routing instance is Internet routing table `inet.0`. If you do not specify a routing instance, the TWAMP probe applies to all routing instances. To apply the TWAMP probe to only the default routing instance, you must explicitly set the value of instance-name to default. If an interface is not part of any routing instance, the default port is used for TWAMP probes. You can configure up to 100 routing instances for a TWAMP server.

Options

instance-name—Name of the routing instance, a maximum of 31 characters.

number—Port number.

- **Range:** 1 through 65,535

Required Privilege Level

system—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

routing-instance (Port Mirroring)

IN THIS SECTION

- Syntax | **15953**
- Hierarchy Level | **15953**
- Description | **15954**
- Required Privilege Level | **15954**
- Release Information | **15954**

Syntax

```
routing-instance instance-name;
```

Hierarchy Level

```
[edit forwarding-options] analyzer name output]
[edit forwarding-options port-mirroring [instance name] family inet output interface name]
```

Description

Configure a port mirroring instance. You do not specify an input for this instance. Instead, you, create a firewall filter that specifies the required traffic and directs it to the mirror. This instance type is useful for controlling which types of traffic should be mirrored.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.3.

routing-instance (PPPoE Service Name Tables)

IN THIS SECTION

- Syntax | 15954
- Hierarchy Level | 15955
- Description | 15955
- Options | 15955
- Required Privilege Level | 15955
- Release Information | 15955

Syntax

```
routing-instance routing-instance-name;
```

Hierarchy Level

```
[edit protocols pppoe service-name-tables table-name service service-name],
[edit protocols pppoe service-name-tables table-name service service-name agent-specifier aci
circuit-id-string ari remote-id-string]
```

Description

Use in conjunction with the `dynamic-profile` statement at the same hierarchy levels to specify the routing instance in which to instantiate a dynamic PPPoE interface. You can associate a routing instance with a named service entry, `empty` service entry, or `any` service entry configured in a PPPoE service name table, or with an agent circuit identifier/agent remote identifier (ACI/ARI) pair defined for these services.

The routing instance associated with a service entry in a PPPoE service name table overrides the routing instance associated with the PPPoE underlying interface on which the dynamic PPPoE interface is created.

If you include the `routing-instance` statement at the `[edit protocols pppoe service-name-tables` *`table-name`* `service` *`service-name`* `agent-specifier aci` *`circuit-id-string`* `ari` *`remote-id-string`*`]` hierarchy level, you cannot also include the `static-interface` statement at this level. The `routing-instance` and `static-interface` statements are mutually exclusive for ACI/ARI pair configurations.

Options

`routing-instance-name`—Name of the routing instance in which the router instantiates the dynamic PPPoE interface.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.2.

routing-instance (Security Destination NAT)

IN THIS SECTION

- Syntax | 15959
- Hierarchy Level | 15960
- Description | 15960
- Options | 15960
- Required Privilege Level | 15960
- Release Information | 15960

Syntax

```
routing-instance (routing-instance-name | default);
```

Hierarchy Level

```
[edit security nat destination pool pool-name]
```

Description

Specify the routing instance on which to perform the route lookup for the address in the pool. It is not a mandatory flag.

A destination NAT pool that does not specify a specific routing instance will default to the routing instance of the ingress zone. You can configure a NAT pool to exist in the default routing instance. As a result, the NAT pool is reachable from zones in the default routing instance and from zones in other routing instances.

Options

routing-instance-name	Name of the routing instance.
default	Use the default routing instance.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement modified in Junos OS Release 9.6.

routing-instance (Security Source NAT)

IN THIS SECTION

- Release Information | 15961

Syntax

```
routing-instance routing-instance-name;
```

Hierarchy Level

```
[edit security nat source pool pool-name]
```

Description

Specify the routing instance to which the pool is bound. It is not a mandatory flag. If the user does not configure the routing instance, by default the pool belongs to routing-instance `inet.0`.

Options

routing-instance-name—Name of the routing instance.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement modified in Junos OS Release 9.6.

routing-instance (Syslog)

IN THIS SECTION

- Syntax | 15962
- Hierarchy Level | 15962
- Description | 15962
- Required Privilege Level | 15963
- Release Information | 15963

Syntax

```
routing-instance routing-instance-name;
```

Hierarchy Level

```
[edit system syslog],
[edit system syslog host ip-address]
```

Description

Configure the routing instance name for the routing instance that you want the syslog client to use. If you want to use the reserved non-default management routing instance mgmt_junos, make sure you configure the `management-instance` statement.

NOTE: You must also define the routing instance you want to use under the `[edit routing-instances]` hierarchy level.

Starting in Junos OS Evolved Release 20.1R1 and 19.4R2, if you are sending syslog messages to a remote host that is identified by its IP address at the `[edit system syslog host ip-address]` hierarchy, you only need to configure the `management-instance` statement to use the mgmt_junos routing instance. You do not need to configure the mgmt_junos routing instance at the `[edit system syslog host ip-address routing-instance]` hierarchy.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 18.4R1.

routing-instances (Logical Systems)

IN THIS SECTION

- Syntax | 15966
- Hierarchy Level | 15966
- Description | 15967
- Default | 15967
- Options | 15967
- Required Privilege Level | 15967
- Release Information | 15967

Syntax

```
routing-instances routing-instance-name { ... }
```

Hierarchy Level

```
[edit],
[edit logical-systems logical-system-name]
```

Description

Configure an additional routing entity for a router or switch. You can create multiple instances of BGP, IS-IS, OSPF, OSPF version 3 (OSPFv3), and RIP for a router or switch.

Default

Routing instances are disabled for the router or switch.

Options

routing-instance-name—Name of the routing instance, a maximum of 31 characters. The remaining statements are explained separately.

non-forwarding-vrf—Enable this option to not create a routing and forwarding (VRF) table for local or transit routes belonging to the given VPN.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

routing-instances (CoS)

IN THIS SECTION

- Syntax | 15972
- Hierarchy Level | 15972

- Description | 15972
- Default | 15973
- Options | 15973
- Required Privilege Level | 15973
- Release Information | 15973

Syntax

```
routing-instances routing-instance-name {
    classifiers {
        dscp (classifier-name | default);
        dscp-ipv6 (classifier-name | default);
        exp (classifier-name | default);
        ieee-802.1 (classifier-name | default);
        no-default;
    }
    policy-map policy-map-name {
    }
}
```

Hierarchy Level

```
[edit class-of-service]
```

Description

For routing instances with VRF table labels enabled, apply a DSCP, MPLS EXP, or IEEE 802.1 classifier to the routing instance. You can apply the default classifier or one that is previously defined.

Apply the `no-default` option to disable the application of any default classifier to the routing instance.

You can also apply a policy map that defines the rewrite rules for a routing instance.

Default

If you do not include this statement with the `classifiers` option, the default MPLS EXP classifier is applied to the routing instance. When no DSCP classifier is configured, the default MPLS EXP classifier is applied.

Options

`routing-instance-name`—Name of the routing instance.

`classifier-name`—Name of the behavior aggregate DSCP, MPLS EXP, or IEEE 802.1 classifier.

`policy-map-name`—Name of the policy map that defines the rewrite rules for a routing instance.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

`no-default` and `policy-map` options added in Junos OS Release 16.1.

routing-instances (Multiple Routing Entities)

IN THIS SECTION

- Syntax | 15976
- Hierarchy Level | 15976
- Description | 15977
- Default | 15977
- Options | 15977
- Required Privilege Level | 15978
- Release Information | 15978

Syntax

```
routing-instances routing-instance-name { ... }
```

Hierarchy Level

```
[edit],
[edit logical-systems logical-system-name]
```

Description

Configure an additional routing entity for a router. You can create multiple instances of BGP, IS-IS, OSPF, OSPFv3, and RIP for a router. You can also create multiple routing instances for separating routing tables, routing policies, and interfaces for individual wholesale subscribers (retailers) in a Layer 3 wholesale network.

Each routing instance consist of the following:

- A set of routing tables
- A set of interfaces that belong to these routing tables
- A set of routing option configurations

Each routing instance has a unique name and a corresponding IP unicast table. For example, if you configure a routing instance with the name `my-instance`, its corresponding IP unicast table is my-instance.inet.0. All routes for `my-instance` are installed into my-instance.inet.0.

Routes are installed into the default routing instance inet.0 by default, unless a routing instance is specified.

In Junos OS Release 9.0 and later, you can no longer specify a routing-instance name of *primary*, *default*, or *bgp* or include special characters within the name of a routing instance.

In Junos OS Release 9.6 and later, you can include a slash (/) in a routing-instance name only if a logical system is not configured. That is, you cannot include the slash character in a routing-instance name if a logical system other than the default is explicitly configured. Routing-instance names, further, are restricted from having the form `__.*__` (beginning and ending with underscores). The colon : character cannot be used when multitopology routing (MTR) is enabled.

Default

Routing instances are disabled for the router.

Options

routing-instance-name	—Name of the routing instance. This must be a non-reserved string of not more than 128 characters.
remote-vtep-list	Configure static remote VXLAN tunnel endpoints.
remote-vtep-v6-list	Configure static IPv6 remote VXLAN tunnel endpoints.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

`remote-vtep-v6-list` statement introduced in Junos OS Release 17.3 for MX Series routers with MPC and MIC interfaces.

[edit logical-systems logical-system-name routing-instances routing-instance-name bridge-domains
bridge-domain-name],
[edit routing-instances routing-instance-name bridge-domains bridge-domain-name]
```

Description

(MX Series routers only) Specify a routing interface to include in a bridge domain or a VPLS routing instance.

When you configure `routing-interface irb.x`, the VPLS connection comes up, even if no customer edge (CE) interfaces are configured. This works with one site configured, but not when multiple sites (multisite) are configured.

Options

routing-interface-name—Name of the routing interface to include in the bridge domain or the VPLS routing instance. The format of the routing interface name is **irb.*x***, where ***x*** is the unit number of the routing interface you configured at the `[edit interfaces irb]` hierarchy level. For more information about how to configure a routing interface, see the Junos OS Network Interfaces Library for Routing Devices.

> **NOTE**: You can specify only one routing interface for each bridge domain or VPLS instance.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.4.

Support for logical systems added in Junos OS Release 9.6.

Syntax

```
routing-service (disable <:$junos-routing-services> | enable<:$junos-routing-services>);
```

Hierarchy Level

```
[edit dynamic-profiles profile-name interfaces interface-name unit logical-unit-name]
```

Description

Enable configuration of additional routing protocols required by client connections on dynamically created enhanced subscriber management interfaces.

NOTE: When clients use only the standard access-internal routes, access routes, and framed routes, you do not need to configure routing services. In other words, the routing service configuration is not required for simple client reachability purposes.

NOTE: You do not need to configure routing services for Internet Group Management Protocol (IGMP) and the Multicast Listener Discovery (MLD) protocol because these protocols are natively supported on enhanced subscriber management interfaces.

NOTE: `routing-service` is supported for the Layer 2 Tunneling Protocol (L2TP) network server subscribers and Point-to-Point Protocol over Ethernet (PPPoE) subscribers. Any other access models, otherwise mentioned, for example aggregated inline service interface, Multilink Point-to-Point Protocol (MLPPP) over L2TP network server (LNS) are not supported.

`routing-service` is not supported for pseudowire subscriber interfaces.

Enable configuration of all routing protocols except Internet Group Management Protocol (IGMP) and the Multicast Listener Discovery (MLD) protocol on dynamically created enhanced subscriber management interfaces. IGMP and MLD are natively supported on enhanced subscriber management interfaces, and therefore do not require you to specify the `routing-service` statement in the dynamic profile.

When a dynamic profile containing the `routing-service` statement is instantiated, the router creates an enhanced subscriber management logical interface, also referred to as a pseudo logical interface, in the form demux0.*nnnnnnnnnn* (for example, demux0.3221225472). Any associated subscriber routes or

routes learned from a routing protocol running on the enhanced subscriber management interface use this pseudo interface as the next-hop interface.

> **NOTE**: The `routing-service` statement replaces the deprecated "routing-services" on page 15991 statement. If you upgrade to Junos OS Release 18.4R1 or higher with a configuration that has active subscribers with "routing-services" on page 15991 enabled, then routing services remain enabled for those subscribers. For all new subscribers after the upgrade, you must use the "routing-service" on page 15988 statement.

You can specify the $junos-routing-services predefined variable to determine, per subscriber, whether routing services can be enabled or disabled by the value of the Routing-Services VSA (26-212) returned in the RADIUS Access-Accept message during subscriber authentication. A value of 0x0000 disables installation of routing services. A value of 0x0001 enables the installation of routing services. Any other value is rejected.

> **NOTE**: The `routing-service` statement is not supported for DHCP dynamic profiles. Do not enable it for DHCP dynamic profiles. However, if the `routing-service` statement is enabled for a dynamic VLAN profile, that VLAN can stack DHCP subscribers.

Options

disable	Disable routing services for all subscribers instantiated on the interface by the profile.
disable:$junos-routing-services	Prevent routing services from being enabled or disabled by the value of the Routing-Services VSA (26-212) for the subscriber being authenticated.
enable	Enable routing services for all subscribers instantiated on the interface by the profile.
enable:$junos-routing-services	Allow routing services to be enabled or disabled by the value of the Routing-Services VSA (26-212) for the subscriber being authenticated.

Description

Enable configuration of additional routing protocols required by client connections on dynamically created enhanced subscriber management interfaces.

NOTE: When clients use only the standard access-internal routes, access routes, and framed routes, you do not need to configure routing services. In other words, the routing service configuration is not required for simple client reachability purposes.

NOTE: You do not need to configure routing services for Internet Group Management Protocol (IGMP) and the Multicast Listener Discovery (MLD) protocol because these protocols are natively supported on enhanced subscriber management interfaces.

NOTE: `routing-services` is supported only for the Layer 2 Tunneling Protocol (L2TP) network server subscribers. Any other access models, otherwise mentioned, for example aggregated inline service interface, Multilink Point-to-Point Protocol (MLPPP) over L2TP network server (LNS) are not supported.

When a dynamic profile containing the `routing-services` statement is instantiated, the router creates an enhanced subscriber management logical interface, also referred to as a pseudo logical interface, in the form demux0.*nnnnnnnnnn* (for example, demux0.3221225472). Any associated subscriber routes or routes learned from a routing protocol running on the enhanced subscriber management interface use this pseudo interface as the next-hop interface.

NOTE: Starting in Junos OS Release 18.4R1, the `routing-services` statement is deprecated. It is replaced by the `routing-service` statement. If you upgrade to Junos OS Release 18.4R1 or higher with a configuration that has active subscribers with "routing-services" on page 15991 enabled, then routing services remain enabled for those subscribers. For all new subscribers after the upgrade, you must use the "routing-service" on page 15988 statement.

NOTE: The `routing-services` statement is not supported for DHCP dynamic profiles. Do not enable it for DHCP dynamic profiles. However, if the `routing-services` statement is enabled for a dynamic VLAN profile, that VLAN can stack DHCP subscribers.

Default

Configuration of additional routing protocols associated with the client connection is disabled by default on enhanced subscriber management dynamic interfaces when you do not include this statement in the dynamic profile.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 15.1R3.

Statement deprecated in Junos OS Release 18.4R1.

RELATED DOCUMENTATION

Junos OS Enhanced Subscriber Management

routing (System Processes)

IN THIS SECTION

- Syntax | 15993
- Hierarchy Level | 15994
- Description | 15994
- Default | 15994
- Options | 15994
- Required Privilege Level | 15995
- Release Information | 15995

Syntax

```
routing {
    force-32-bit | force-64-bit | auto-64-bit;
}
```

Hierarchy Level

```
[edit system processes],
[edit logical-systems logical-system name system processes]
```

Description

Configure routing protocols process (rpd) mode.

Default

`force-32-bit` mode is used in Junos 15.1F2 and prior releases

`auto-64-bit` mode is used starting in Junos 15.1F3

Options

`auto-64-bit` (Optional) Enable to use 64-bit mode. If the system is 64-bit capable and has at least 16 GB of RAM, then `auto-64-bit` will cause the Routing Engine to run in 64-bit mode. Otherwise, it will run in 32-bit mode.

> **NOTE**: This option is not applicable for logical systems.
> Starting in Junos 15.1F3, 15.1R2, 15.1R3, and 15.2R1, 64-bit mode is enabled by default on systems that support it and which have at least 16 GB of RAM.

`force-32-bit` (Optional) Enable to always use 32-bit mode.

> **NOTE**: For MX Series routers, virtual private LAN service (VPLS) dynamic profiles are not supported with the 64-bit mode routing protocol process (rpd). To enable VPLS dynamic profiles configuration, configure the routing process to use 32-bit mode.

`force-64-bit` (Optional) Enable to always use 64-bit mode.

> **TIP**: You need not restart the routing protocol process (rpd) to use the 64-bit mode. However, forcing rpd from 32-bit to 64-bit or 64-bit-to 32-bit will restart the rpd process, which can impact the routing protocols. For this reason, it is recommended to perform these changes in a maintenance window.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

[edit interfaces interface-name unit logical-unit-number family inet6]
```

Description

Enable a reverse-path forwarding (RPF) check on unicast traffic.

On EX3200 and EX4200 switches, enable a reverse-path forwarding (RPF) check on unicast traffic (except ECMP packets) on all ingress interfaces.

On EX4300 switches, enable a reverse-path forwarding (RPF) check on unicast traffic, including ECMP packets, on all ingress interfaces.

On EX8200 and EX6200 switches, enable an RPF check on unicast traffic, including ECMP packets, on the selected ingress interfaces.

On MX204 and ACX7k devices, `strict` is the default mode unless you over-ride it by setting the option to `loose`.

On QFX Series switches, enable an RPF check on unicast traffic on the selected ingress interfaces. ECMP packets are checked by QFX5000 Series switches only.

The mode statement is explained separately.

Default

Unicast RPF is disabled on all interfaces.

Options

`fail-filter`—A filter to evaluate when packets are received on the interface. If the RPF check fails, this optional filter is evaluated. If the fail filter is not configured, the default action is to silently discard the packet.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Support for interface `ps0` (pseudowire subscriber logical interface device) added in Junos OS Release 15.1.

rpf-check (Dynamic Profiles)

IN THIS SECTION

- Syntax | **16010**
- Hierarchy Level | **16010**

- Description | 16010
- Required Privilege Level | 16011
- Release Information | 16011

Syntax

```
rpf-check {
    fail-filter filter-name;
    mode loose;
}
```

Hierarchy Level

```
[edit dynamic-profiles profile-name interfaces interface-name unit logical-unit-number family
family]
```

Description

Reduce forwarding of IP packets that might be spoofing and address by checking whether traffic is arriving on an expected path that the sender would use to reach the destination. You can include this statement with the `inet` protocol family only. When the traffic passes the check, it is forwarded to the destination address; otherwise it is discarded. When you configure `rpf-check` alone, then unicast RPF is in strict mode, meaning that the check passes only when the packet's source address is in the FIB and the interface matches the routes RPF.

Starting in Junos OS Release 19.1, the `show interfaces statistics` *`logical-interface-name`* `detail` command displays unicast RPF statistics for dynamic logical interfaces when either `rpf-check` or `rpf-check mode loose` is enabled on the interface. No additional statistics are displayed when `rpf-check fail-filter` *`filter-name`* is configured on the interface. The `clear interfaces statistics` *`logical-interface-name`* command clears RPF statistics.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.6.

Syntax

```
rpf-check-policy policy;
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options multicast],
[edit routing-options multicast]
```

Description

Enable you to control whether a reverse path forwarding (RPF) check is performed for a source and group entry before installing a route in the multicast forwarding cache. This makes it possible to use point-to-multipoint LSPs to distribute multicast traffic to Protocol Independent Multicast (PIM) islands situated downstream from the egress routers of the point-to-multipoint LSPs.

Options

policy—Name of the RPF check routing policy.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.0.

rpf-vector (PIM)

IN THIS SECTION

- Syntax | 16018
- Hierarchy Level | 16018
- Description | 16018
- Options | 16018
- Required Privilege Level | 16018
- Release Information | 16019

Syntax

```
rpf-vector {
    policy (rpf-vector)[ policy-name];
}
```

Hierarchy Level

```
[edit dynamic-profiles name protocols pim],
[edit logical-systems name protocols pim],
[edit logical-systems name routing-instances name protocols pim],
[edit protocols pim],
[edit routing-instances name protocols pim]
```

Description

This feature provides a way for PIM source-specific multicast (SSM) to resolve Vector Type Length (TLV) for multicast in a seamless Multiprotocol Label Switching (MPLS) networks. In other words, it enables PIM to build multicast trees through an MPLS core. `rpf-vector` implements RFC 5496, Reverse Path Forwarding (RPF) Vector TLV .

When `rpf-vector` is enabled on an edge router that sends PIM join messages into the core, the join message includes a vector specifying the IP address of the next edge router along the path to the root of the multicast distribution tree (MDT). The core routers can then process the join message by sending it towards the specified edge router (i.e., toward the Vector). The address of the edge router serves as the RPF vector in the PIM join message so routers in the core can resolve the next-hop towards the source without the need for BGP in the core.

Only the IPv4 address family is supported.

Options

policy Create a filter policy to determine whether or not to apply `rpf-vector`.

Required Privilege Level

routing

Release Information

Statement introduced in Junos OS Release 17.3R1.

```

Description

Configure the generation of multiple IPv4 RPM tests for a probe owner. Starting in Junos OS Release 18.2R1, you can also configure the generation of multiple IPv6 RPM tests for a probe owner. Tests are generated for multiple combinations of source and target addresses, which are incremented based on your configuration. Tests are first generated for all the source addresses with the initial target address, then tests are generated for all the source addresses with the next available target address, and so on.

Options

interface-name.logical-unit-number	The services interface that is generating RPM probes and the logical unit number that is used for the first test that is generated.
ipv4-address-base	The IPv4 source or target address that is incremented to generate the addresses used in the RPM tests.
ipv4-count	The maximum number of IPv4 source or target addresses to use for the generated RPM tests.
ipv4-step	The amount to increment the IPv4 source or target address for each generated RPM test.
ipv6-address-base	The IPv6 source or target address that is incremented to generate the addresses used in the RPM tests.
ipv6-count	The maximum number of IPv6 source or target addresses to use for the generated RPM tests.
ipv6-step	The amount to increment the IPv6 source or target address for each generated RPM test.
subunit-cnt	The maximum number of logical units used by the services interface in the generated tests. The first generated test uses the logical unit specified in the *interface-name.logical-unit-number* option, and each successive test increments the logical unit number by one. Once the maximum number of logical units has been used, the next generated test cycles back to the logical unit that was used in the first test.

tests-count

The maximum number of RPM tests to generate. This number must be less than or equal to the number of generated source addresses multiplied by the number of generated target addresses.

- **Range:** 1 through 500,000 for probes generated on an MS-MPC or MS-MIC.
  1 through 2,000 for probes generated on the Routing Engine.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 17.4R1.

[edit services monitoring]
```

Description

Configure real-time performance monitoring (RPM). RPM enables you to configure active probes to track and monitor traffic. Probes collect packets per destination and per application, including PING Internet Control Message Protocol (ICMP) packets, User Datagram Protocol and Transmission Control Protocol (UDP/TCP) packets with user-configured ports, user-configured Differentiated Services code point (DSCP) type-of-service (ToS) packets, and Hypertext Transfer Protocol (HTTP) packets. RPM provides Management Information Base (MIB) support with extensions for RFC 2925, *Definitions of Managed Objects for Remote Ping, Traceroute, and Lookup Operations*.

Starting in Junos OS Evolved Release 20.1R1, you can configure RPM probes. For Junos OS Evolved, RPM is configured at the `[edit services monitoring rpm]` hierarchy level. The scope of support is limited to:

- Probe generation and reception (client) as well as reflection (server) for the following RPM probe types:
  - icmp-ping
  - icmp-timestamp
  - udp-ping
  - udp-timestamp
- Probe history management

- Reporting through syslog only

Starting in Junos OS Evolved 20.3R1, you can configure TWAMP probes. Starting in Junos OS Evolved 21.1R1, you can configure RFC 2544 benchmarking tests. For Junos OS Evolved, TWAMP is configured at the `[edit services monitoring twamp]` hierarchy level and RFC 2544 benchmarking tests are configured at the `[edit services monitoring rfc2544]` hierarchy level.

Starting in Junos OS Evolved Release 21.2R1, reporting through SNMP MIB objects is supported for RPM.

Starting in Junos OS Evolved Release 23.4R1, you can configure `tcp-ping`, `http-get`, and `http-metadata-get` probe types.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Evolved Release 20.1R1.

`traps` option introduced in Junos OS Evolved Release 21.2R1.

`source-address` option and the `local-link` sub-option of the `target-address` option for TWAMP Light test sessions introduced in Junos OS Release 21.4R1.

`tcp` sub-option for the `probe-server` option introduced in Junos OS Evolved Release 23.4R1.

`tcp-ping`, `http-get`, and `http-metadata-get` probe types introduced in Junos OS Evolved Release 23.4R1.

Change History Table

Feature support is determined by the platform and release you are using. Use Feature Explorer to determine if a feature is supported on your platform.

Release	Description
23.4R1 Evo	Starting in Junos OS Evolved Release 23.4R1 for the ACX7024, ACX7100, ACX7332, ACX7348, ACX7509, PTX10001-36MR, PTX10003, PTX10004, PTX10008, PTX10016, QFX5130-32CD, QFX5130-48C, QFX5130-48CM, QFX5220, and QFX5700, you can configure `tcp-ping`, `http-get`, and `http-metadata-get` probe types for RPM.
21.4R1	Starting in Junos OS Release 21.4R1, you can configure RPM and TWAMP probes for EX9200 switches.
21.4R1	Starting in Junos OS Release 21.4R1, for TWAMP Light test-sessions on MX and PTX routers, you can configure IPv6 link-local target addresses and their corresponding source addresses.
21.3R1	Starting in Junos OS 21.3R1, you can configure RPM and TWAMP probes for QFX10000 Series switches.
21.2R1 Evo	Starting in Junos OS Evolved Release 21.2R1, reporting through SNMP MIB objects is supported for RPM.
21.1R1 Evo	Starting in Junos OS Evolved 21.1R1, you can configure RFC 2544 benchmarking tests.
20.3R1 Evo	Starting in Junos OS Evolved 20.3R1, you can configure TWAMP probes.
20.1R1 Evo	Starting in Junos OS Evolved Release 20.1R1, you can configure RPM probes. For Junos OS Evolved, RPM is configured at the [edit services monitoring rpm] hierarchy level.

rpm-tracking

IN THIS SECTION

- Syntax | 16038
- Hierarchy Level | 16038
- Description | 16038
- Options | 16039
- Required Privilege Level | 16040
- Release Information | 16040

Syntax

```
rpm-tracking {
    route destination-prefix {
        metric metric;
        next-hop next-hop {;
           rpm-probe name rpm-test test-name;
        }
        preference preference;
        tag tag;
    }
 }
```

Hierarchy Level

```
[edit routing-instances name routing-options],
[edit routing-options]
```

Description

RPM-tracked static routes are coupled with a given RPM test instance. Routes can be installed or removed according to the results of the given RPM test. When installed, these routes are automatically

given a preference of 1, and so are preferred over static routes that may already exist with the same prefix.

If the RPM test result is “success,” then all the RPM-tracked static routes that match the probe owner and test name of the successful test are added to the routing table. If the test result is “failure,” then all the RPM-tracked static routes that match the probe owner and test name of the failed test are removed, if present, from the routing table.

RPM route tracking supports both IPv4 and IPv6 routes. RPM-tracked static routes are configured individually; wildcards, ranges, and regular expressions are not supported.

Options

route ***destination-prefix***
(Required) Configure an RPM-tracked static route. Must be a IPv4 or IPv6 destination prefix.

next-hop ***next-hop***
(Required) Configure a next-hop address. Must be a IPv4 or IPv6 address. You can configure up to 16 multiple paths (next-hops) for any given RPM-tracked static route (RPM-tracked static routes with multiple next-hops can also be configured inside a routing instance).

metric ***metric***
(Optional) Set the route metric for the destination prefix. The route with the lowest metric is active in the routing table.

- **Default:** 1
- **Range:** 1 through 16.

preference ***preference***
(Optional) Set the route preference value for the destination prefix. The route with the lowest preference value is active in the routing table. Qualified next hops are not supported with RPM-tracked static routes. Hence, the setting of the `preference`, `metric`, and `tag` options apply only to the RPM-tracked static route and not to the related next hops.

- **Default:** 1

tag ***tag***
(Optional) Set the route tag value for the destination prefix. The route with the lowest tag value is active in the routing table.

- **Default:** 0

rpm-probe ***name***
(Required) Must be a valid RPM probe owner from the `[edit services rpm]` configuration hierarchy.

rpm-test *test-name* (Required) Must be a valid RPM test name from the `[edit services rpm]` configuration hierarchy.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Support introduced in Junos OS Release 18.4 R1.

`next-hop` option added in Junos OS Release 19.1R1.

`preference` and `tag` options added in Junos OS Release 20.4R1.

Description

Use rendezvous-point trees for customer PIM (C-PIM) join messages, and switch to the shortest-path tree after the source is known.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.0.

rsh

IN THIS SECTION

- Syntax | 16042
- Hierarchy Level | 16042
- Description | 16042
- Options | 16042
- Required Privilege Level | 16043

Release Information | 16043

Syntax

```
rsh {
    disable;
    traceoptions {
        flag {
            all {
                extensive
            }
        }
    }
}
```

Hierarchy Level

```
[edit logical-systems name security alg],
[edit logical-systems name tenants name security alg],
[edit security alg],
[edit services alg],
[edit tenants name security alg]
```

Description

Configure rsh to specify the remote shell (RSH) ALG on the device. The Remote Shell (RSH) provides a conduit to execute commands on a remote host.

Options

- `disable`—Disable the RSH ALG. By default, the RSH ALG is disabled.
- `traceoptions`—Configure RSH ALG tracing options.
  - `flag`—Trace operation to perform.
    - `all`—Trace all events.

- *extensive*—Display extensive amount of data.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.5.

The `tenant` option is introduced in Junos OS Release 18.3R1.

rst-invalidate-session

IN THIS SECTION

- Syntax | 16043
- Hierarchy Level | 16044
- Description | 16044
- Required Privilege Level | 16044
- Release Information | 16044

Syntax

```
rst-invalidate-session;
```

Hierarchy Level

```
[edit security flow tcp-session]
```

Description

Enable the device to mark a session for immediate termination when it receives a TCP reset (RST) message. By default, this feature is disabled.

> **NOTE**: On SRX Series Firewalls with `rst-invalidate-session` configured the invalidation of the session occurs immediately whereas without `rst-invalidate-session` configured the session is set to time out 2 seconds after a TCP reset (RST) message has been received.

Required Privilege Level

security—To view this in the configuration.

security-control—To add this to the configuration.

Release Information

Statement introduced in Junos OS Release 8.5.

rst-sequence-check

IN THIS SECTION

- Syntax | 16045
- Hierarchy Level | 16045
- Description | 16045

Required Privilege Level | 16045
Release Information | 16045

Syntax

```
rst-sequence-check;
```

Hierarchy Level

```
[edit security flow tcp-session]
```

Description

Verify that the TCP sequence number in a TCP segment with the RST bit enabled matches the previous sequence number for a packet in that session or is the next higher number incrementally. If the sequence number does not match either of these expected numbers, the device drops the packet and sends the host a TCP ACK message with the correct sequence number. By default, this check is disabled.

Required Privilege Level

security—To view this in the configuration.

security-control—To add this to the configuration.

Release Information

Statement introduced in Junos OS Release 8.5.

Description

Configure Rapid Spanning Tree Protocol (RSTP). RSTP is defined in the IEEE 802.1D-2004 specification and is used to prevent loops in Layer 2 networks, which results in shorter convergence times than those provided by basic Spanning Tree Protocol (STP).

VSTP and RSTP can be configured concurrently. You can selectively configure up to 253 VLANs using VSTP; the remaining VLANs will be configured using RSTP. VSTP and RSTP are the only spanning-tree protocols that can be configured concurrently on the switch.

BEST PRACTICE: Configure RSTP when you configure VSTP. RSTP overhead is minimal and this configuration ensures that a spanning-tree protocol is running on all VLANs on your switch, even when your switch is supporting more than 253 VLANs.

The remaining statements are explained separately. See CLI Explorer.

Default

RSTP is enabled on all Ethernet switching interfaces.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.4.

`bpdu-block-on-edge` statement added in Junos OS Release 9.4.

`bpdu-timeout-action` statement added in Junos OS Release 9.4.

Support for logic systems added in Junos OS Release 9.6.

Statement updated in Junos OS Release 15.1 for EX Series and QFX Series switches to support configuration of spanning tree parameters globally on all interfaces.

NOTE: You cannot disable spanning tree parameters globally on all interfaces.

```

Description

Enable Resource Reservation Protocol (RSVP) signaling.

You must include the `rsvp` statement in the configuration to enable RSVP on the router.

The primary purpose of RSVP in Junos OS for EX Series switches is to support dynamic signaling within label switched paths (LSPs).

Options

`cross-credibility-cspf`—Enable path computation across credibility levels. The constraint path computation is run across multi-protocol links and nodes, instead of a credibility-by-credibility basis.

`authentication key`—Authentication key. Neighboring routers use the password to verify the authenticity of packets sent from this interface or peer interface. It is recommended to use the `authentication-key` configuration at the `[edit protocols rsvp]` hierarchy level for the RSVP node-neighbor.

`graceful deletion timeout`—Specify the time, in seconds, before completing graceful deletion of signaling.

`graceful restart`—Configure `graceful restart` on the router. You must configure the `graceful-restart` statement at the `[edit routing-options]` hierarchy level to enable graceful restart on the router.

`hello acknowledgements`—Enable hello messages from nonsession neighbors to be acknowledged with a hello acknowledgment message. Once `hello acknowledgments` are enabled, the router continues to acknowledge hello messages from any nonsession RSVP neighbors unless the interface itself goes down or the configuration is changed by an administrator.

`interface`—Enable RSVP on one or more router interfaces.

`bandwidth`—Enables you to specify the actual available bandwidth.

`hello interval`—Enable the sending of hello packets on the interface.

`link protection`—Using link protection, you can configure a network to reroute traffic quickly around broken links.

`priority`—Configure the setup priority and reservation priority for a bypass LSP.

`exclude-srlg`—Exclude Shared Risk Link Group (SRLG) links for the secondary path for critical links where it is imperative to keep the secondary and primary label-switched paths completely disjoint from any common SRLG.

`hop-limit`—Specify the maximum number of routers that an LSP can traverse. Maximum number of hops.

`bypass`—Enables you to configure specific bandwidth and path constraints for a bypass LSP.

`max bypasses`—Specify the maximum number of dynamic bypass LSPs permitted for protecting this interface.

`no cspf`—Disable CSPF computation on all bypass LSPs or on a specific bypass LSP. You need to disable CSPF for link protection to function properly on interarea paths.

`optimize-timer`—The optimize timer initiates a periodic optimization process that reshuffles data LSPs among bypass LSPs to achieve the most efficient use of network resources.

`path`—Configure an explicit path (a sequence of strict or loose routes) to control where and how a bypass LSP is established.

`update threshold`—Adjust the threshold at which a change in bandwidth triggers an interior gateway protocol (IGP) update.

`keep multiplier`—Indicates the number of messages that can be lost before a particular state is declared stale and must be deleted. The keep multiplier directly affects the lifetime of an RSVP state.

`no authentication check`—Skip authentication check for received messages.

`node hello`—Enable node-ID based RSVP hellos globally on all of the RSVP interfaces on the router to allow Juniper Networks routers to interoperate with the equipment of other vendors.

`peer interface`—Configure the name of the LMP peer device.

`no-enhanced-frr-bypass`—Enable `no-enhanced-frr-bypass` to turn off all Fast reroute (FRR) facility protection enhancements, which includes improved LSP scaling and enhanced RSVP message handling, and reduce the default refresh time to 30 seconds.

`no-interface-hello`—Explicitly disable RSVP interface hellos globally on the router.

`no-local-reversion`—Disable RSVP local revertive mode as specified in RFC 4090, Fast Reroute Extensions to RSVP-TE for LSP Tunnels.

`no-node-hello-on-bypass`—Starting with Junos release 16.1, Junos routers send RSVP hello packets over a bypass LSP (when one is present), instead of the IGP next hop. To return to the original behavior specify the `no-node-hello-on-bypass` option.

`no-node-id-subobject`—Disable the record route object (RRO) node-ID subobject for compatibility with earlier versions of Junos OS.

`pop-and-forward`—Specify RSVP pop-and-forward LSP tunnel-specific global parameters.

`refresh time`—Periodical refresh timer expressed in seconds.

`setup-protection`—The facility-backup fast reroute mechanism can provide setup protection for LSPs which are in the process of being signaled.

`traceoptions`—The default RSVP-level trace options are those inherited from the routing protocols `traceoptions` statement included at the `[edit routing-options]` hierarchy level.

`tunnel services`—The Junos OS selects one of the available virtual tunnel (VT) interfaces to de-encapsulate the egress traffic.

Default

RSVP is disabled.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

rsvp-error-hold-time

IN THIS SECTION

- Syntax | 16056
- Hierarchy Level | 16056
- Description | 16057
- Options | 16057
- Required Privilege Level | 16057
- Release Information | 16057

Syntax

```
rsvp-error-hold-time seconds;
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols mpls],
[edit protocols mpls]
```

Description

Amount of time MPLS retains RSVP PathErr messages and considers them for CSPF computations. The more time you configure, the more time a source node (ingress of an RSVP LSP) can have to learn about the failures of its LSP by monitoring PathErr messages transmitted from downstream nodes.

Information from the PathErr messages is incorporated into subsequent LSP computations, which can improve the accuracy and speed of LSP setup. Some PathErr messages are also used to update traffic engineering database bandwidth information, reducing inconsistencies between the database and the network.

Options

seconds—Amount of time MPLS retains RSVP PathErr messages and considers them for CSPF computations.

- **Range:** 0 through 240 seconds
- **Default:** 25 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Syntax

```
rtf-prefix-list name route-targets
```

Hierarchy Level

```
[edit logical-systems logical-system-name policy-options],
[edit logical-systems logical-system-name policy-options policy-statement policy-name term term-
name],
```

```
[edit policy-options],
[edit policy-options policy-statement policy-name term term-name]
```

Description

Define a list of route target prefixes for use in a routing policy statement. These prefixes are only useful for filtering routes in the bgp.rtarget.0 table.

The route target filtering prefix is in the format: *AS number:route target extended community/length*. The first number represents the autonomous system (AS) of the device that sent the advertisement. The second group of numbers represent the route target extended community. The format of the extended community is the same as the extended community type `target:`. For more information about extended communities, see *Understanding How to Define BGP Communities and Extended Communities* .

In this route target prefix example 64500:200:101/96, 64500 is the AS number, 200:101 is the BGP extended community used for the route target, and 96 is the prefix length.

For more information about the route target community, see RFC 4360, *BGP Extended Communities Attribute*.

For more information about the route target filtering prefix format, see RFC 4684, *Constrained Route Distribution for Border Gateway Protocol/MultiProtocol Label Switching (BGP/MPLS) Internet Protocol (IP) Virtual Private Networks (VPNs)*.

Options

name—Name that identifies the list of route target filtering prefixes. The name can contain letters, numbers, and hyphens (-) and can be up to 255 characters long. To include spaces in the name, enclose the entire name in quotation marks (“ “).

route-targets—List of route target filtering prefixes, one route target filter per line in the configuration. When you use the `rtf-prefix-list` statement as a match condition, you do not have the option of configuring the list of route target filtering prefixes. You must first define and configure the route target filtering prefixes with the `policy-options` statement.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.2.

rule-activation-time

IN THIS SECTION

- Syntax | 16078
- Hierarchy Level | 16078
- Description | 16078
- Options | 16079
- Required Privilege Level | 16079
- Release Information | 16079

Syntax

```
rule-activation-time {
    <day-of-week | day-of-month month>;
    <hour:min>;
}
```

Hierarchy Level

```
[edit unified-edge pcef pcc-time-of-day-profiles profile-name]
```

Description

Specify the time of day, day of the week or day of the month, or month of the year to activate a PCC rule or rulebase. You can specify the time of day, the day, or both. If you specify the day of the month, you can also specify the month of the year, which results in the yearly activation of the rule or rulebase. Use the same combination of options in the `rule-deactivation-time` statement. If a time zone is configured on the router, the time-of-day settings apply to the configured time zone.

If a day is not specified and the activation time of day setting is later than the deactivation time of day setting, then a rule is deactivated the day after it is activated.

Options

day-of-week (Optional) Day of the week on which to activate a PCC rule or rulebase.

day-of-month (Optional) Day of the month on which to activate a PCC rule or rulebase.

- **Syntax: DAY*n***, where *n* can be from 1 through 31, or **Last-day-of-month**, which depends on the current month.

month (Optional) Month of the year in which to activate a PCC rule or rulebase.

hour (Optional) Hour at which to activate a PCC rule or rulebase as a two-digit number from 00 through 23.

min (Optional) Minute at which to activate a PCC rule or rulebase as a two-digit number from 00 through 59.

Required Privilege Level

unified-edge—To view this statement in the configuration.

unified-edge-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 17.1.

Syntax

```
rule rule-name {
    disable-midstream-routing;
    match {
        category (juniper-enhanced-category | custom-category);
        dynamic-application [system-application | any];
        dynamic-application-group [system-application-group];
        dscp dscp-value;
    }
    then {
        application-services-bypass;
        routing-instance name;
        sla-rule sla-rule-name;
    }
}
```

Hierarchy Level

[edit security advance-policy-based-routing profile *profile-name*]

Description

Configure rules for the advanced policy-based routing (APBR) profile (application profile). Associate the rule with one or more than one dynamic applications or application groups or URL categories as follows:

- For matching the dynamic applications, APBR consults the application identification (AppID) and application system cache (ASC) to get the application type. If the application matches any of the application or application groups of a rule in a profile, the application profile rule is considered to be a match, and the traffic is redirected to the defined routing instance for the route lookup.
- You can use a DSCP value in an APBR rule as a matching criteria to perform advanced policy-based routing on the traffic with DSCP markings. You can use the DSCP value in addition to the dynamic applications in an APBR rule.
- For matching the URL categories, APBR leverages category identification from the Enhanced Web Filtering (EWF) and local Web filtering results obtained from the Content Security module. Web filtering classifies websites into categories. If the traffic matches the URL categories specified in the rule of the APBR profile, it is redirected to the defined routing instance.

Options

disable-midstream-routing Selectively disable APBR in the middle of a session for a specific APBR rule.

match Define a match criteria for matching the traffic in APBR profile rule.

- **category (*juniper-enhanced-category* | *custom-category*)** Define the category type as the Juniper Enhanced Web Filtering (EWF) or a custom category if you are using local Web filtering.
  - ***juniper-enhanced-category*** Define URL categories such as Enhanced_Social_Web_Facebook, Enhanced_Social_Web_Linkedin, Enhanced_Social_Web_Twitter or Enhanced_Social_Web_Youtube as match criteria in APBR profile rule.
  - ***custom-category*** Define either custom URL or IP address of a site as match criteria in APBR profile rule.
- **dynamic-application [*system-application* | any]** Specify the dynamic application names for match criteria in APBR rule.

dynamic-application-group [*system-application-group*]	Dynamic application groups for match criteria in APBR rule.
dscp [*dscp-value*]	Specify DSCP value as match criteria in APBR rule. • **Range:** 0-63

then Define the action for the match condition by specifying the routing instance name.

application-services-bypass	Bypass applying the application services on the traffic matching the APBR rule. As URL category-based routing enables you to identify and selectively route Web traffic (HTTP and HTTPS) to a specified destination or to another device where further inspection, you can select not to apply or bypass application services on the same session. You can select to exclude traffic from security services when additional throughput is required, or traffic is going from trusted device to another trusted device.
routing-instance *name*	Name of the routing instance for redirecting traffic.
sla-rule *name*	Name of the SLA rule to apply on the traffic.

Required Privilege Level

services—To view this statement in the configuration.

services-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 15.1X49-D60. The option `category` is introduced in Junos OS Release 18.3R1. Junos OS Release 19.3R1 supports the option `dscp`. Junos OS Release 20.1R1 supports the option `any` for `dynamic-application`.

rule (Application Firewall)

IN THIS SECTION

- Syntax | 16083
- Hierarchy Level | 16083
- Description | 16084
- Options | 16084
- Required Privilege Level | 16085
- Release Information | 16085

Syntax

```
rule rule-name {
    match {
        dynamic-application [system-application];
        dynamic-application-groups [system-application-group];
        ssl-encryption (any | yes | no);
    }
    then {
        deny {
            block-message block-message;
        }
        permit permit;
        reject {
            block-message block-message;
        }
    }
}
```

Hierarchy Level

```
[edit security application-firewall  rule-sets name ]
```

Description

Specify rules for application firewall.

You need to create rules to permit, reject, or deny traffic for dynamic applications to configure application firewall rule sets within the security policy. The application firewall support in the policies provides additional security control for dynamic applications.

Starting in Junos OS Release 18.2R1 application firewall (AppFW) functionality is deprecated. As a part of this change, the `[edit security application-firewall]` hierarchy and all the configuration options under this hierarchy are deprecated— rather than immediately removed—to provide backward compatibility and a chance to bring your configuration into compliance with the new configuration.

Options

match Specify security rule match-criteria

dynamic-application Select dynamic applications as match criteria.

dynamic-application-group Select dynamic applications group as match criteria.

ssl-encryption Select SSL encryption rules as match criteria.

- Values:
  - `any`—Encrypted and non-encrypted rule.
  - `no`—Non-encrypted rule.
  - `yes`—Encrypted rule.

then Specify the action to be performed when traffic matches the associated match criteria.

deny Block the traffic at the firewall. The device drops the packet. By default, no message is returned to the sender.

block-message ***block-message*** (Optional) In application firewall rules, provide information to the user regarding blocked traffic. Depending on the content of the `profile` option for this rule set, including the `block-message` option displays a default message or customized message, or redirects the user for denied HTTP or HTTPS traffic. All other traffic is dropped silently.

reject Block the traffic at the firewall. For TCP traffic, by default the device drops the packet and returns a TCP reset (RST) message to the source host. For UDP and other protocol

traffic, by default the device drops the packet and returns an ICMP “destination unreachable, port unreachable” message to both the client and the server.

block-message *block-message* (Optional) In application firewall rules, provide information to the user regarding blocked traffic. Depending on the content of the `profile` option for this rule set, including the `block-message` option displays a default message or customized message, or redirects the user for denied HTTP or HTTPS traffic. All other traffic is dropped silently.

permit Permit traffic at the firewall.

Required Privilege Level

security

Release Information

Statement introduced in Junos OS Release 11.1. Statement updated in Junos OS Release 12.1X44-D10 to include the `ssl-encryption` and `reject` options. The `block-message` options added in Junos OS Release 12.1X45-D10.

rule (casb-policy)

IN THIS SECTION

- Syntax | 16088
- Hierarchy Level | 16088
- Description | 16089

- Options | 16089
- Required Privilege Level | 16089
- Release Information | 16089

Syntax

```
rules rule-name {
    match {
          application application-name {
        activity activity-name {
        [param-name param-value param-name param-value]
        }
    instance instance-name;
       }
      application-group application-group-name {
             activity activity-name
         }
    }
    then {
    allow;
       deny;
       log-action;
    }
}
```

Hierarchy Level

```
[edit security casb casb-policy policy-name]
```

Description

Configure Cloud Access Security Broker (CASB) policy rule. CASB policy rule includes set of match criteria defining the conditions that must be satisfied to apply the policy and a set of actions to be performed in case of a match—allow, deny, or log actions.

Options

match *rule-name*

Define a match criteria for matching the traffic in CASB policy rule. You can specify following:

- application *application-name*—Enter the supported application name.
- application-group *application-group-name*—Enter the supported application-group name.
- activity—Configure activity-parameters for shared-activity option. You can configure this optional statement to have even more granular control over traffic.
- instance *instance-name*—Enter an application instance.

then

Define the action for the match condition by specifying—allow/deny and log-actions.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 24.2R1.

rule-deactivation-time

IN THIS SECTION

- Syntax | 16090
- Hierarchy Level | 16090

- Description | 16090
- Options | 16090
- Required Privilege Level | 16091
- Release Information | 16091

Syntax

```
rule-deactivation-time {
    <day-of-week | day-of-month month>;
    <hour:min>;
}
```

Hierarchy Level

```
[edit unified-edge pcef pcc-time-of-day-profiles profile-name]
```

Description

Specify the time of day, day of the week or day of the month, or month of the year to deactivate a PCC rule or rulebase. You can specify the time of day, the day, or both. If you specify the day of the month, you can also specify the month of the year, which results in the yearly deactivation of the rule or rulebase. Use the same combination of options as in the `rule-activation-time` statement. If a time zone is configured on the router, the time-of-day settings apply to the configured time zone.

If a day is not specified and the deactivation time of day setting is earlier than the activation time of day setting, then a rule is deactivated the day after it is activated.

Options

day-of-week (Optional) Day of the week on which to deactivate a PCC rule or rulebase.

day-of-month (Optional) Day of the month on which to deactivate a PCC rule or rulebase.

- **Syntax: DAY*n***, where *n* can be from 1 through 31, or **Last-day-of-month**, which depends on the current month.

month (Optional) Month of the year in which to deactivate a PCC rule or rulebase.

hour (Optional) Hour at which to deactivate a PCC rule or rulebase as a two-digit number from 00 through 23.

min (Optional) Minute at which to deactivate a PCC rule or rulebase as a two-digit number from 00 through 59.

Required Privilege Level

unified-edge—To view this statement in the configuration.

unified-edge-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 17.1.

Configuring Protection Against Network Attacks on an MS-MPC

rule (IP Reassembly)

IN THIS SECTION

- Syntax | 16100
- Hierarchy Level | 16100
- Description | 16100
- Options | 16101
- Required Privilege Level | 16101
- Release Information | 16101

Syntax

```
rule rule-name {
    match-direction direction;
}
```

Hierarchy Level

```
[edit services ip-reassembly]
```

Description

Configure an IP reassembly rule, which is used for inline IP reassembly on the inline services interface. The IP reassembly rule can be attached to a service set to indicate that the service set is of type IP reassembly. For inline IP reassembly, each rule must include the `match-direction` statement, which specifies the direction in which the match is applied.

NOTE: If you configure an IP reassembly rule, then you must configure the `match-direction` statement.

> **NOTE**: To create more than one IP reassembly rule, include the `rule` statement multiple times.

Options

rule-name Name of the IP reassembly rule.

- **Range:** Up to 63 characters

The remaining statement is explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 13.1.

Support added in Junos OS Release 19.3R2 for Next Gen Services on MX Series routers MX240, MX480 and MX960 with the MX-SPC3 services card.

rule (LRF)

IN THIS SECTION

Syntax | 16102

- Hierarchy Level | 16102
- Description | 16102
- Options | 16102
- Required Privilege Level | 16103
- Release Information | 16103

Syntax

```
rule lrf-rule-name {
    then {
        report {
            collector collector-name;
            template template-name;
            time-limit time-interval;
            volume-limit volume;
        }
    }
}
```

Hierarchy Level

```
[edit services lrf profile profile-name]
```

Description

Configure an LRF rule, which controls how data sessions are logged and reported. In this release, the matching conditions for an LRF rule are identified in a static PCC rule, not in the LRF rule.

Options

lrf-rule-name

Name of the LRF rule.

- **Range:** Up to 63 characters.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 17.1.

Support for Next Gen Services introduced in Junos OS Release 19.3R1 on MX Series.

rule (PCP)

IN THIS SECTION

- Syntax | 16104
- Hierarchy Level | 16104
- Description | 16104
- Options | 16105
- Required Privilege Level | 16105
- Release Information | 16105

Syntax

```
rule rule-name {
    match-direction (input | output);
    term term-name {
        from {
            application-sets set-name;
            applications [ application-name ];
            destination-address address <except>;
            destination-address-range high maximum-value low minimum-value <except>;
            destination-port  high maximum-value low minimum-value;
            destination-prefix-list list-name <except>;
            source-address address <except>;
            source-address-range high maximum-value low minimum-value <except>;
            source-prefix-list list-name <except>;
        }
        then {
            pcp-server server-name;
        }
    }
    }
}
```

Hierarchy Level

```
[edit services pcp]
```

Description

Configure a rule to assign the port control protocol (PCP) server that handles selected traffic. PCP enables hosts to operate servers for a long time (as in the case of a webcam) or a short time (for example, while playing a game or on a phone call) when behind a NAT device, including when behind a carrier-grade NAT operated by their ISP. PCP enables applications to create mappings from an external IP address and port to an internal IP address and port.

PCP is supported on the MS-DPC, MS-100, MS-400, and MS-500 MultiServices PICS. Starting in Junos OS Release 17.4R1, PCP is also supported on the MS-MPC and MS-MIC.

Options

rule-name	Rule name

The remaining statements are explained separately.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 13.2R1.

    }
}
```

Hierarchy Level

```
[edit security idp idp-policy policy-name rulebase-ips]
```

Description

Specify IPS rule to create, modify, delete, and reorder the rules in a rulebase.

Options

rule-name—Name of the IPS rulebase rule.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.2.

Starting in Junos OS Release 18.2R1, IDP policy is available within unified security policy. When IDP policy is available within the unified security policy then the IDP polciy configurations are simplified. Configuring source or destination address, source and destination-except, from and to zone, or application is not required with unified policy, as the match happens in the security policy itself.

Additional tags under filters of dynamic attack groups are added in Junos OS Release 18.2R1 for dynamic attacks grouping of IDP signatures.

rule (Security Source NAT)

            }
        }
    }
}
```

Hierarchy Level

```
[edit services cos]
```

Description

Configure a services CoS rule, which specifies Differentiated Services (DiffServ) code point (DSCP) marking and forwarding-class assignment for packets that are processed by a service set. The CoS rule identifies the matching conditions for packet source and destination addresses and for packet applications, and the actions to take on those packets.

The service set that the CoS rule is assigned to must include at least one stateful firewall rule or NAT rule, or CoS does not work. Only stateful firewall and NAT rules can be used with CoS rules in a service set.

Options

match-direction (input | input-output | output) The direction in which the rule is matched.

- **input** Apply the rule match on input. If the CoS rule is assigned to an interface service set, input means traffic entering the interface. If the CoS rule is assigned to a next-hop service set, input means traffic routed with the inside interface.
- **input-output** Apply the rule match in both directions.
- **output** Apply the rule match on output. If the CoS rule is assigned to an interface service set, input means traffic leaving the interface. If the CoS rule is assigned to a next-hop service set, output means traffic routed with the outside interface.

rule-name Name of the CoS rule.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 19.3R2.

        }
    }
}
```

Hierarchy Level

```
[edit services nat],
[edit services nat rule-set rule-set-name]
```

Description

Specify the rule the router uses when applying this service.

NOTE: You are limited to a maximum of 200 terms for a NAT rule that is applied to an inline services (type si) interface. If you specify more than 200 terms, you will receive following error when you commit the configuration:

```
[edit]
  'service-set service-set-name'
    NAT rule rule-name  with more than 200 terms is disallowed for si-n/n/n.n
error: configuration check-out failed
```

Options

rule-name Identifier for the collection of terms that make up this rule.

The remaining statements are explained separately.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Configuring Stateful Firewall Rules

rule-session-count-alarm (Security Destination NAT Rule Set)

IN THIS SECTION

- Syntax | 16124
- Hierarchy Level | 16124
- Description | 16124
- Options | 16124
- Required Privilege Level | 16125
- Release Information | 16125

Syntax

```
rule-session-count-alarm (clear-threshold value | raise-threshold value):
```

Hierarchy Level

```
[edit security nat destination rule-set rule-set-name rule rule-name then destination-nat]
```

Description

Define session count alarm thresholds for a specific Network Address Translation (NAT) destination rule. When the session count exceeds the upper (raise) threshold or falls below the lower (clear) threshold, an SNMP trap is triggered.

Options

clear-threshold *value* Lower threshold at which an SNMP trap is triggered.

raise-threshold *value* Upper threshold at which an SNMP trap is triggered.

> **NOTE**: If you enter a value for **raise-threshold** but not for **clear-threshold**, **clear-threshold** is automatically set to 80 percent of **raise-threshold**.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.1X45-D10.

rule-session-count-alarm (Security Source NAT Rule Set)

IN THIS SECTION

- Syntax | 16125
- Hierarchy Level | 16126
- Description | 16126
- Options | 16126

Syntax

```
rule-session-count-alarm (clear-threshold value | raise-threshold value);
```

Hierarchy Level

```
[edit security nat static rule-set rule-set-name rule rule-name then static-nat ]
```

Description

Define session count alarm thresholds for a specific static Network Address Translation (NAT) rule. When the session count exceeds the upper (raise) threshold or falls below the lower (clear) threshold, an SNMP trap is triggered.

Options

clear-threshold *value* Lower threshold at which an SNMP trap is triggered.

raise-threshold *value* Upper threshold at which an SNMP trap is triggered.

NOTE: If you enter a value for `raise-threshold` but not for `clear-threshold`, `clear-threshold` is automatically set to 80 percent of `raise-threshold`.

Required Privilege Level

Statement introduced in Junos OS Release 10.4.

RELATED DOCUMENTATION

Configuring Softwire Rules

rule-set (Softwires Next Gen Services)

IN THIS SECTION

- Syntax | 16147
- Hierarchy Level | 16148
- Description | 16148
- Options | 16148
- Required Privilege Level | 16148
- Release Information | 16148

Syntax

```
rule-set rule-set-name {
    match-direction (input | output);
    rule rule-name {
        then {
            ds-lite ds-lite-concentrator-name
            map-e map-e-concentrator-name
            v6rd v6rd-softwire-concentrator;
        }

    }
}
```

Hierarchy Level

```
[edit services softwires]
```

Description

Configure a rule to apply a DS-Lite, MAP-E, or v6rd softwire concentrator to a flow.

Options

input	Apply the rule on the input side of the interface.
output	Apply the rule on the output side of the interface.
rule *rule-name*	Name of the rule.
rule-set *rule-set-name*	Name of the rule set that contains the rule.
ds-lite *ds-lite-softwire-concentrator*	Name of the softwire concentrator that the rule assigns to a flow.
map-e *map-e-softwire-concentrator*	Name of the softwire concentrator that the rule assigns to a flow.
v6rd *v6rd-softwire-concentrator*	Name of the softwire concentrator that the rule assigns to a flow.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 19.3R2.

```

Description

Defines AppQoS rule sets and the rules that establish priorities based on quality-of-service requirements for the associated applications. AppQoS rules can be included in policy statements to implement application-aware quality of service control.

Options

- *rule-set-name*—Name used to refer to a collection of AppQoS rules.
- rule *rule-name*—Name applied to the match criteria and resulting actions that control the quality-of-service provided to any matching applications.
- application *application-name*—Name of the application to be used as match criteria for the rule.
- application-any —Any application encountering this rule. Note that when you use this specification, all application matching ends. Any application rule following this one will never be encountered.
- application-group *application-group-name*—Group of applications to be used as match criteria for the rule. Both applications and application groups can be match criteria for a single rule.
- application-known—Match criteria specifying any session that is identified, but its corresponding application is not specified.
- application-unknown—Match criteria specifying any session that is not identified.
- forwarding-class *forwarding-class-name*—The AppQoS class with which matching applications will be marked. This field identifies the rewriter that has marked the DSCP value . Therefore, the AppQoS forwarding class must be different from those used by IDP or firewall filters. With this class specified, firewall filter class will not overwrite the existing DSCP value.
- dscp-code-point—DSCP alias or bit map with which matching applications will be marked to establish the output queue. This value can be marked by rewriters from IDP, AppQoS, or a firewall filter. The

forwarding-class value identifies which rewriter has re-marked the packet with the current DSCP value. If a packet triggers all three rewriters, IDP takes precedence over AppQoS, which takes precedence over a firewall filter.

- `loss-priority`—Loss priority with which matching applications will be marked. This value is used to determine the likelihood that a packet would be dropped when encountering congestion. A high loss priority means that there is an 80% chance of packet loss in congestion. Possible values are high, medium-high, medium-low and low.
- `rate-limit`—Rate limiters to be associated with client-to-server and with server-to-client traffic for this application. The rate limiter profile defines maximum speed and volume limits for matching applications.
- `log`—AppQoS event logging.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.4.

Support at the following hierarchy levels introduced in Junos OS Release 19.3R1: `[edit logical-systems` *`logical-system-name`* `class-of-service application-traffic-control]`, and `[edit tenants` *`tenant-name`* `class-of-service application-traffic-control]`.

        }
    }
}
```

Hierarchy Level

```
[edit security application-firewall]
```

Description

Configure the set of rules for the application firewall.

The application firewall is defined by a collection of rule sets. These rule sets can be defined independently and shared across network security policies. A rule set defines the rules that specify match criteria, including dynamic applications, and the action to be taken for matching traffic.

To implement an application firewall, you need to:

- Define one or more application firewall rule sets.
- Create rules for each rule set that permit, reject, or deny traffic based on the application ID.
- Configure a security policy to invoke the application firewall service and specify the rule set to be applied to permitted traffic.

The application firewall support in the policies provides additional security control for dynamic applications.

Starting in Junos OS Release 18.2R1, the application firewall (AppFW) functionality is deprecated. As a part of this change, the `[edit security application-firewall]` hierarchy and all the configuration options under this hierarchy are deprecated— rather than immediately removed—to provide backward compatibility and an opportunity to bring your configuration into compliance with the new configuration.

Options

rule-set-name	Name of the rule set.
profile *profile-name*	Profile for block message.
default-rule	Specify default rule.
rule	Specify security rule match-criteria

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.1. Statement updated in Junos OS Release 12.1X44-D10 to include the `ssl-encryption` and `reject` options. The `block-message` options added in Junos OS Release 12.1X45-D10.

rule (Softwire)

IN THIS SECTION

- Syntax | **16154**
- Hierarchy Level | **16155**
- Description | **16155**
- Options | **16155**
- Required Privilege Level | **16155**
- Release Information | **16155**

Syntax

```
rule rule-name {
    match-direction (input | output);
    term term-name {
        then {
            (ds-lite ds-lite-softwire-concentrator | map-e name | v6rd v6rd-softwire-
concentrator);
        }
    }
}
```

Hierarchy Level

```
[edit  services softwire],
[edit  services softwire rule-set rule-set-name]
```

Description

Configure a rule to apply a softwire concentrator for a flow.

Softwire rules are supported on the MS-DPC, MS-100, MS-400, and MS-500 line cards. Starting in Junos OS release 17.4R1, softwire rules for DS-Lite are supported on MX Series routers with MS-MPCs and MS-MICs.

Options

rule-name	Identifier for the collection of terms that constitute this rule.
input	Apply the rule match on the input side of the interface.
output	Apply the rule match on the output side of the interface.
ds-lite-softwire-concentrator	Specify the DS-Lite softwire concentrator to use.
map-e *name*	Specify the Mapping of Address and Port with Encapsulation (MAP-E) softwire concentrator to use.
v6rd-softwire-concentrator	Specify the 6rd softwire concentrator to use.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.4.

`map-e` *name* option introduced in Junos OS Release 18.2R1 for MX Series Routers with MPC and MIC interfaces.

rx-buffers

IN THIS SECTION

- Syntax | **16165**
- Hierarchy Level | **16165**
- Description | **16165**
- Default | **16165**
- Options | **16166**
- Required Privilege Level | **16166**
- Release Information | **16166**

Syntax

```
rx-buffers (on | off);
```

Hierarchy Level

```
[edit interfaces interface-name ether-options configured-flow-control]
```

Description

Enable or disable an interface to generate and send Ethernet PAUSE messages. If you enable the receive buffers to generate and send PAUSE messages, when the receive buffers reach a certain level of fullness, the interface sends a PAUSE message to the connected peer. If the connected peer is properly configured, it stops transmitting frames to the interface on the entire link. When the interface receive buffer empties below a certain threshold, the interface sends a message to the connected peer to resume sending frames.

Ethernet PAUSE prevents buffers from overflowing and dropping packets during periods of network congestion. If the other devices in the network are also configured to support PAUSE, PAUSE supports lossless operation. Use the `rx-buffers` statement with the `tx-buffers` statement to configure asymmetric Ethernet PAUSE on an interface. (Use the `flow-control` statement to enable symmetric PAUSE and the `no-flow-control` statement to disable symmetric PAUSE on an interface. Symmetric flow control and asymmetric flow control are mutually exclusive features. If you attempt to configure both, the switch returns a commit error.)

> **NOTE**: Ethernet PAUSE temporarily stops transmitting all traffic on a link when the buffers fill to a certain threshold. To temporarily pause traffic on individual “lanes” of traffic (each lane contains the traffic associated with a particular IEEE 802.1p code point, so there can be eight lanes of traffic on a link), use priority-based flow control (PFC).
>
> Ethernet PAUSE and PFC are mutually exclusive features, so you cannot configure both of them on the same interface. If you attempt to configure both Ethernet PAUSE and PFC on an interface, the switch returns a commit error.

Default

Flow control is disabled. You must explicitly configure Ethernet PAUSE flow control on interfaces.

Options

`on | off`—Enable or disable an interface to generate and send Ethernet PAUSE messages.

Required Privilege Level

interface—To view this statement in the configuration.

- Description | 16171
- Options | 16171
- Required Privilege Level | 16172
- Release Information | 16172

Syntax

```
rx-window-size packets;
```

Hierarchy Level

```
[edit services l2tp tunnel]
```

Description

Configure the L2TP receive window size for an L2TP tunnel.

Options

packets—Number of packets that a peer can transmit without receiving an acknowledgment from the router. By default, this value is set to 4 packets. If the receive window size is configured to its default value, the router does not send the Receive Window Size AVP (AVP 10) in the first tunnel negotiation packet that is sent to its peer.

- **Range:** 4 through 128
- **Default:** 4

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 13.3.

RELATED DOCUMENTATION

L2TP Tunnel Switching For Multiple-Domain Networks

L2TP LAC Subscriber Configuration

L2TP LNS Inline Service Interfaces

s-nssai

IN THIS SECTION

- Syntax | 16259
- Hierarchy Level | 16259
- Description | 16259
- Options | 16260
- Required Privilege Level | 16260
- Release Information | 16260

Syntax

```
s-nssai name {
 sd sd;
 sst(embb | miot | urllc | v2x);
}
```

Hierarchy Level

```
[edit services agf tracking-area name plmn]
```

Description

Configure the single network slice selection assistance information (S-NSSAI). The S-NSSAI is used to uniquely identify a network slice. It consists of two components. For a fixed network residential gateway (FN-RG), the Access Gateway Function (AGF) sends a proxy S-NSSAI message to the Access and Mobility Management Function (AMF) during the initial setup.

- SST—Slice service type
- SD—Selection differentiator

Options

name Single network slice selection assistance information identifier

- **Range:**0 through 128

sd Selection differentiator

- **Default:** 0
- **Range:** 0 through 16777215

sst Slice service type

- embb—Enhanced mobile broadband slice
- miot—Massive Internet of Things (IoT)
- urllc—Ultra-reliable, low-latency communications
- v2x—V2X services

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 22.3R1.

s6a

IN THIS SECTION

- Syntax | **16261**
- Hierarchy Level | **16261**
- Description | **16261**

- Options | 16261
- Required Privilege Level | 16262
- Release Information | 16262

Syntax

```
s6a {
    partition name {
        destination-host destination-host;
        destination-realm destination-realm;
        diameter-instance diameter-instance;
        max-outstanding-requests max-outstanding-requests;
        response-timeout seconds;
    }
}
```

Hierarchy Level

```
[edit access]
```

Description

S6a is a Diameter-based authentication application used by the Mobility Management Entity (MME) nodes to retrieve authentication information from Home Subscriber Server (HSS). Specify the destination and transmission parameters for the S6a protocol.

Options

destination-host Name of the host where the S6A server application resides; generally, this value is not set unless needed.

destination-realm Name of the realm where the S6a server application resides.

diameter-instance Specifies that the master Diameter instance is used. `master` is the only supported value.

max-outstanding-requests

Configure the maximum number of outstanding requests for the S6a application.

- **Default:** 40
- **Range:** 2 through 1024

response-timeout

Configure the amount of time (in seconds) that the MME waits to receive a response from the HSS.

- **Default:** 15
- **Range:** 1 through 30

Required Privilege Level

access

Release Information

Statement introduced in Junos OS Release 19.3R1.

[edit routing-instances instance-name protocols msdp group group-name peer address]
[edit routing-instances instance-name protocols msdp peer address]
```

Description

Specify the source address (SA) message hold time to use when maintaining a connection with the MSDP peer. Each entry in an SA cache has an associated hold time. The hold timer is started when an SA message is received by an MSDP peer. The timer is reset when another SA message is received before the timer expires. If another SA message is not received during the SA message hold-time period, the SA message is removed from the cache.

You might want to change the SA message hold time for consistency in a multi-vendor environment.

Options

seconds—Source address message hold time.

- **Range:** 75 through 300 seconds
- **Default:** 75 seconds

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.3.

Syntax

```
sa-multicast;
```

Hierarchy Level

```
[edit chassis fpc slot pic slot forwarding-mode]
```

Description

Configure the 100-Gigabit Ethernet PIC or MIC to interoperate with other Juniper Networks 100-Gigabit Ethernet PICs.

> **NOTE**: The default packet steering mode for PD-1CE-CFP-FPC4 is SA multicast bit mode. No SA multicast configuration is required to enable this mode.

sa-multicast supports interoperability between the following PICs and MICs:

- 100-Gigabit Ethernet Type 5 PIC with CFP (PF-1CGE-CFP) and the 100-Gigabit Ethernet Type 4 PIC with CFP (PD-1CE-CFP-FPC4) .
- 100-Gigabit Ethernet MICs and the 100-Gigabit Ethernet Type 4 PIC with CFP (PD-1CE-CFP-FPC4).

Required Privilege Level

interface—To view this statement in the configuration.

    }
    routing-instance routing-instance;
    t3-response seconds;
}
```

Hierarchy Level

```
[edit services mobile-edge gateways saegw]
```

Description

Use this section to define the connection to and characteristics of data plane peers.

Options

local-address

Required. IPv4 address(es) of the local end of the GTP-U connection.

> **NOTE**: There is no limit to the number of data plane peers that can connect to the SAEGW-U.

n3-requests

Number of retries of peer management request messages upon `t3-response` timeout.

- **Range:** 1 through 5
- **Default:** 3

routing-instance

Local routing instance of the GTP-U connection.

> **NOTE**: If at least one peer group is used, eNodeBs matching only the peer group address/prefix are accepted by the SAEGW-U/SGW-U during session establishment. The eNodeB is bound to the routing instance within the "peer-groups" on page 12361 stanza, if available. Otherwise, the SAEGW-U/SGW-U uses the routing instance provided here.

t3-response Waiting time before retrying peer management request upon response timeout (seconds).

- **Range:** 1 through 5
- **Default:** 5

The remaining statements are explained separately. See CLI Explorer.

control-plane-peers {
    apn-services {
        apns name {
            mobile-interface mobile-interface;
            source-validation {
        }
    }
    heartbeat-interval seconds;
    local-address [ local-address ... ];
    n3-requests n3-requests;
    path-management (disable | enable);
    peer-groups name {
        heartbeat-interval seconds;
        initiate-association;
        n3-requests n3-requests;
        path-management (disable | enable);
        peer {
            address [ address ... ];
            hostname hostname;
        }
        routing-instance routing-instance;
        t3-response seconds;
    }
    response-cache-timeout seconds;
    routing-instance routing-instance;
    t3-response seconds;
}
```

Hierarchy Level

```
[edit services mobile-edge gateways saegw]
```

Description

Use this section to define the connection to and characteristics of control plane peers (SAEGW-C, SGW-C, or PGW-C).

Options

heartbeat-interval

Time between two successive heartbeat requests (seconds).

- **Range:** 60 through 255
- **Default:** 60

local-address

Required. IPv6 or IPv4 or both addresses of the local end of the PFCP connection.

> **NOTE**: If you are connecting to multiple control plane peers, define the local address under the `control-plane-peers` stanza for each control plane peer rather than define a single loopback address.

n3-requests

Maximim number of retries of PFCP request messages upon t3-response timeout.

- **Range:** 1 through 5
- **Default:** 3

path-management

Enable/disable origination of heartbeat message requests to control peers.

- **Default:** Disabled

response-cache-timeout

Configure the timeout for the PFCP response cache (seconds).

- **Range:** 0 through 255
- **Default:** 0

routing-instance

Local routing instance of the PFCP. This is used to determine in which routing instance the responses are to be sent for incoming PFCP messages. If a routing instance is not configured:

- Only PFCP messages coming from control plane peers over the default routing instance are handled.
- PFCP responses are only sent in the default routing instance.

- PFCP messages coming over any other routing instance are dropped even if the destination address matches the defined `local-address`.

If a single routing instance is configured:

- Only PFCP messages coming from control plane peers over the configured routing instance are handled.
- PFCP responses are only sent through this routing instance.
- PFCP messages coming over any other routing instance are dropped.

t3-response

Waiting time of gateway before retrying a PFCP signaling-request upon response timeout (seconds).

- **Range:** 1 through 5
- **Default:** 5

The remaining statements are explained separately. See CLI Explorer.

        interface interface-name {
            colocated-4g-pgw;
            colocated-4g-sgw;
        }
    }
    class-of-service {
    ... }
    destination {
    ... }
    service-mode (mobile-edge SAEGW) {
    ... }
}
```

Hierarchy Level

```
[edit services mobile-edge gateways saegw]
```

Description

Define the anchor PFEs for the SAEGW-U. The anchor PFEs are the line cards where the GTP-U data packets from `access-network-peers` are decapsulated and sent towards the SGi interface to the core network. Similarly, packets from the SGi interface are encapsulated in GTP-U by the anchor PFEs and sent towards the RAN.

Options

anchor-pfes Define the anchor PFEs by providing their interface names.

- **Syntax:** interface *interface-name*

colocated-4g-pgw (Optional) Attach the PGW-U gateway type to the anchor PFE to optimize throughput of 4G traffic.

colocated-4g-sgw (Optional) Attach the SGW-U gateway type to the anchor PFE to optimize throughput of 4G traffic.

- Description | 16280
- Default | 16281
- Options | 16281
- Required Privilege Level | 16281
- Release Information | 16281

Syntax

```
sak-rekey-interval seconds;
```

Hierarchy Level

```
[edit security macsec connectivity-association connectivity-association-name mka]
```

Description

Configure a timer-based refresh of the secure association key (SAK) on a MACsec-secured link. This ensures that the SAK is frequently updated, making it less vulnerable to attack.

In static CAK mode, the SAK is generated by the key server and is periodically refreshed. The refresh interval is based on packet counter movement by default. Depending on the amount of traffic and the speed of the interface, it might take a long time for the new SAK to be generated. This can provide enough time for a successful attack on the key. You can enhance security of the SAK by configuring a shorter timer-based refresh interval.

When the MACsec session is live with a primary, preceding, or fallback PSK, or with a key from a key-chain, the SAK refresh will occur based on the configured interval independent of key type in a hitless

way. No traffic drop will occur at the time of the SAK rollover. Refresh of the PSK will occur periodically after every configured SAK refresh interval.

When an XPN cipher suite is configured, the refresh interval configured in the key server takes precedence over the refresh interval configured in the non-key server, even if the interval configured in the non-key server is lower.

Default

The SAK refresh interval is not enabled by default.

Options

seconds The length of the SAK refresh interval in seconds.

- **Range:** 60 through 86,400 seconds

IN THIS SECTION

- Syntax | 16287
- Hierarchy Level | 16287
- Description | 16287
- Required Privilege Level | 16288
- Release Information | 16288

Syntax

```
sample-once;
```

Hierarchy Level

```
[edit forwarding-options sampling]
```

Description

Explicitly sample a packet for active monitoring only once. When you configure the `sample-once` statement, the ingress interface sets a flag for any packets that it selects for sampling, and the egress interface does not sample any flagged packets. Setting this option avoids duplication of packets in cases where sampling is enabled at both the ingress and egress interfaces and simplifies analysis of the sampled traffic.

NOTE: The sampling works independently on the ingress and egress interfaces. If the sample `rate` is 1, the ingress interface samples and flags all packets arriving at the

interface. However, if the sample `rate` is higher than 1, then the ingress interface may sample and flag only a subset of packets, as determined by the configured sampling parameters. The ingress and egress interfaces may contain different sets of packets in their sampling windows. As a result, if the ingress interface does not sample (and flag) a packet in a given sampling window, the egress interface may still sample that same packet as part of its sampling window.

Required Privilege Level

sampling-instance

IN THIS SECTION

- Syntax | 16297
- Hierarchy Level | 16297
- Description | 16297
- Required Privilege Level | 16297
- Release Information | 16298

Syntax

```
sampling-instance instance-name;
```

Hierarchy Level

```
[edit chassis fpc slot-number],
[edit chassis lcc number fpc routing-matrix-slot-number],
[edit chassis member member-number fpc slot slot-number]
```

Description

Associate a defined sampling instance with a specific FPC, MPC, or DPC for active sampling instances configured at the `[edit forwarding-options sampling]` hierarchy level.

For M120 routers with FEB, this statement must also be configured under `[edit chassis feb slot-number]`, in addition to the `[edit forwarding-options sampling]` hierarchy level.

In a two-member MX Series Virtual Chassis, the primary router (member 0) uses FPC slot numbers 0 through 11 with no offset; the backup router (member 1) uses FPC slot numbers 12 through 23, with an offset of 12.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.6.

Support at the `[edit chassis member member-number fpc slot slot-number]` hierarchy level introduced in Junos OS Release 14.1.

sampling (Interfaces)

IN THIS SECTION

- Syntax | **16298**
- Hierarchy Level | **16299**
- Description | **16299**
- Options | **16299**
- Required Privilege Level | **16299**
- Release Information | **16299**

Syntax

```
sampling direction;
```

Hierarchy Level

```
[edit interfaces interface-name unit logical-unit-number family inet],
[edit logical-systems logical-system-name interfaces interface-name unit logical-unit-number
family inet]
```

Description

Configure the direction of traffic to be sampled.

Options

direction can be one of the following:

`input`—Configure at least one expected ingress point.

`output`—Configure at least one expected egress point.

`input output`—On a single interface, configure at least one expected ingress point and one expect egress point.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

sampling (Protocols MPLS)

IN THIS SECTION

- Syntax | 16300
- Hierarchy Level | 16300
- Description | 16300
- Options | 16301
- Required Privilege Level | 16301
- Release Information | 16301

Syntax

```
sampling {
    cut-off-threshold percentile;
    use-average-aggregate;
    use-percentile percentile;
}
```

Hierarchy Level

```
[edit protocols mpls container-label-switched-path lsp-name splitting-merging]
```

Description

Configure traffic sampling. By default, sampling mode is set to `Max Aggregate` which means the system will compare each new sample with the previous sample. If the new sample is higher than the old sample, then the newer sample is considered `Sampled Aggregate bandwidth`

Max Aggregate Example

If normalization happens every 20min (T0, T20, T40..) then if at time T0 the traffic rate is 185Gbps, and subsequently drops to 7.5Gbps at time T3, the max-aggregate sample for the current normalization window T0-T20 will be 185Gbps. When the current normalization window expires at time T20, we use the previous sampled max-aggregate of 185Gbps to calculate the split/merge activities of the next (or

now current) normalization window between T20 – T40. If traffic remains at 7.5Gbps for this second normalization period, then at time T40 the max-aggregate sample of 7.5Gbps would then be used for split/merge activities. Even though traffic volumes dropped at time T3, LSP split/merge activities would not occur until time T40 which might be unexpected. This default behavior can be modified with use-average-aggregate or use-percentile to achieve alternative normalization behavior if desired.

Options

`cut-off-threshold` *`percentile`*

Specify the percentile value to be used as a cut-off threshold in removing outlier bandwidth samples. All the aggregate bandwidth samples determined as outliers are used for computing aggregate bandwidth used at the time of normalization.

- **Default:** 0 percentile (the ingress considers all aggregate bandwidth samples for normlaization.)
- **Range:** 0 through 100

`use-average-aggregate`

Specify the ingress router to take average of the aggregate samples for normalization.

This option is mutually exclusive with the `use-percentile` configuration option.

`use-percentile` *`percentile`*

Specify the ingress router to compute and use the `pth` percentile from all the bandwidth samples, and use that for normalization.

This option is mutually exclusive with the `use-average-aggregate` configuration option.

- **Range:** 0 through 100

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 14.2.

sanity-poll

IN THIS SECTION

- Syntax | 16302
- Hierarchy Level | 16302
- Description | 16303
- Options | 16303
- Required Privilege Level | 16303
- Release Information | 16303

Syntax

```
sanity-poll {
    retry-count number;
    on-error {
        raise-alarm;
        power (cycle | off);
        write-coredump;
    }
}
```

Hierarchy Level

```
[edit chassis cfeb slot-number],
[edit chassis feb slot-number],
[edit chassis fpc slot-number],
[edit chassis lcc number fpc number]
```

Description

Enable sanity polling and start periodic sanity checking for a particular FPC. The periodic sanity check includes checking for error conditions such as “register sanity issues,” “high temperature,” “hardware failure,” and so on in the FPC.

NOTE: Currently, periodic sanity check is performed only on the routing chip register.

Options

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.4.

satellite (Junos Fusion Automatic Satellite Conversion)

IN THIS SECTION

- Syntax | 16305
- Hierarchy Level | 16305
- Description | 16305
- Options | 16306
- Required Privilege Level | 16306
- Release Information | 16306

Syntax

```
satellite [slot-id | range | all];
```

Hierarchy Level

```
[edit chassis satellite-management auto-satellite-conversion]
```

Description

Specify the interface to enable automatic software conversion in a Junos Fusion.

The device that is cabled to the slot specified in this command is automatically converted into a satellite device.

Additional configuration steps are required to add satellite devices to a Junos Fusion using automatic satellite conversion. See Configuring or Expanding a Junos Fusion Enterprise or *Configuring Junos Fusion Provider Edge*.

Options

slot-id Specifies the FPC slot identifier of the device that will be automatically converted into a satellite device.

The FPC identifier must be mapped to a cascade port interface before this command is operational. See Configuring or Expanding a Junos Fusion Enterprise or *Configuring Junos Fusion Provider Edge*.

range Specifies a range of FPC slot identifiers that will automatically be converted into satellite devices. For instance, to specify that FPC IDs 103, 104, and 105 should be automatically converted into satellite devices, enter a *range* of **103-105**.

all Specifies that all FPC slot identifiers in the Junos Fusion will automatically be converted into satellite devices.

Required Privilege Level

admin—To view this statement in the configuration.

IN THIS SECTION

- Syntax | 16307
- Hierarchy Level | 16307
- Description | 16307
- Options | 16307
- Required Privilege Level | 16308
- Release Information | 16308

Syntax

```
satellite [slot-id |slot-id-range | all];
```

Hierarchy Level

```
[edit chassis satellite-management single-home]
```

Description

Specify which satellite device links are single-homed to the aggregation device.

You must enter this statement to configure a Junos Fusion when the aggregation device is running Junos OS Release 14.2R3 or 14.2R4. You are not required to enter this command when the aggregation device is running Junos OS Release 14.2R5 or later.

Options

slot-id Specifies that a link from a specified satellite device is single-homed to the aggregation device. The *slot-id* is the satellite device member number.

slot-id-range	Specifies that the links from a range of specified satellite devices are single-homed to the aggregation device. The *slot-id-range* includes the satellite device member numbers.
all	Specifies that all links from satellite devices are single-homed to the aggregation device.

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 14.2R3.

Statement introdcued in Junos OS Release 16.1R1 for Junos Fusion Enterprise.

Syntax

```
satellite [slot-id | range | all];
```

Hierarchy Level

```
[edit chassis satellite-management upgrade-groups upgrade-group-name]
```

Description

Specify the satellite device to add to the satellite software upgrade group.

This statement is entered on an aggregation device in a Junos Fusion. Software upgrade groups are configured and managed using the aggregation device.

Options

slot-id Specifies the FPC slot identification number of the satellite device that is being added to the satellite software upgrade group.

range Specifies a range of FPC slot identifiers to add to the satellite software upgrade group. For instance, to specify that FPC IDs 103, 104, and 105 should be automatically converted into satellite devices, enter a *range* of **103-105**.

all Specifies that all FPC slot identifiers in the Junos Fusion are added to the satellite software upgrade group.

The remaining statements are explained separately.

save

IN THIS SECTION

- Syntax | 16315
- QFX and VMX Series | 16316
- Description | 16316
- Options | 16316
- Required Privilege Level | 16317
- Release Information | 16317

Syntax

```
save (<dhcp-security-snoop>filename)
```

QFX and VMX Series

```
save (<dhcp-security-snoop | dhcpv6-security-snoop | slaac-security-snoop>filename)
```

Description

Save the configuration to an ASCII file. The contents of the current level of the statement hierarchy (and below) are saved, along with the statement hierarchy containing it. This allows a section of the configuration to be saved, while fully specifying the statement hierarchy.

For information on valid filename and URL formats, see Format for Specifying Filenames and URLs in Junos OS CLI Commands.

When saving a file to a remote system, the software uses the `scp/ssh` protocol.

Options

filename—Name of the saved file. You can specify a filename in one of the following ways:

- *filename*—File in the user's home directory (the current directory) on the local flash drive.
- *path/filename*—File on the local flash drive.
- `/var/`*filename* or `/var/`*path/filename*—File on the local hard disk.
- `a:`*filename* or `a:`*path/filename*—File on the local drive. The default path is `/` (the root-level directory). The removable media can be in MS-DOS or UNIX (UFS) format.
- *hostname:/path/filename*, *hostname:filename*, *hostname:path/filename*, or `scp://` *hostname/path/filename*—File on an `scp/ssh` client. This form is not available in the worldwide version of Junos OS. The default path is the user's home directory on the remote system. You can also specify *hostname* as *username@hostname*.
- `ftp://`*hostname/path/filename*—File on an FTP server. You can also specify *hostname* as *username @hostname* or *username*:*password @hostname*. The default path is the user's home directory. To specify an absolute path, the path must start with the string `%2F`; for example, `ftp://`*hostname/%2Fpath/filename*. To have the system prompt you for the password, specify `prompt` in place of the password. If a password is required, and you do not specify the password or `prompt`, an error message is displayed:

```
user@host> file copy ftp://username@ftp.hostname.net//filename
file copy ftp.hostname.net: Not logged in.
user@host> file copy ftp://username:prompt@ftphostname.net//filename
```

Password for *username*@ftp.*hostname*.net:

- `http://hostname/path/filename`—File on a Hypertext Transfer Protocol (HTTP) server. You can also specify *hostname* as *username@hostname* or *username:password@hostname*. If a password is required and you omit it, you are prompted for it.
- `re0:/path/filename` or `re1:/path/filename`—File on a local Routing Engine.

Options for QFX and VMX Series

- `dhcp-security-snoop`—Save DHCP snooping entries
- `dhcpv6-security-snoop`—Save DHCPv6 snooping entries
- `slaac-security-snoop`—Slaac-Snooping security entries

Required Privilege Level

> **NOTE**: The `save` commands for `dhcp-security-snoop`, `dhcpv6-security-snoop`, and `slaac-security-snoop` are restricted to admin only.

- Syntax | **16318**
- Description | **16318**

- Options | 16318
- Required Privilege Level | 16319
- Sample Output | 16319
- Release Information | 16319
- Hierarchy Level | 16320

Syntax

```
save filename
```

Description

Save the configuration to an ASCII file. The contents of the current level of the statement hierarchy (and below) are saved, along with the statement hierarchy containing it. This allows a section of the configuration to be saved, while fully specifying the statement hierarchy.

For information on valid filename and URL formats, see Format for Specifying Filenames and URLs in Junos OS CLI Commands.

When saving a file to a remote system, the software uses the scp/ssh protocol.

Options

filename—Name of the saved file. You can specify a filename in one of the following ways:

- *filename*—File in the user's home directory (the current directory) on the local flash drive.
- *path/filename*—File on the local flash drive.
- /var/*filename* or /var/*path/filename*—File on the local hard disk.
- a:*filename* or a:*path/filename*—File on the local drive. The default path is / (the root-level directory). The removable media can be in MS-DOS or UNIX (UFS) format.
- *hostname:/path/filename*, *hostname:filename*, *hostname:path/filename*, or scp:// *hostname/path/filename*—File on an scp/ssh client. This form is not available in the worldwide version of Junos OS. The default path is the user's home directory on the remote system. You can also specify *hostname* as *username@hostname*.

- `ftp://hostname/path/filename`—File on an FTP server. You can also specify *hostname* as *username* `@`*hostname* or *username*:*password*`@`*hostname*. The default path is the user's home directory. To specify an absolute path, the path must start with the string `%2F`; for example, `ftp://hostname/%2F`*path*/*filename*. To have the system prompt you for the password, specify `prompt` in place of the password. If a password is required, and you do not specify the password or `prompt`, an error message is displayed:

```
user@host> file copy ftp://username@ftp.hostname.net//filename
file copy ftp.hostname.net: Not logged in.
user@host> file copy ftp://username:prompt@ftphostname.net//filename
```

Password for *username*@ftp.*hostname*.net: `re0:/path/filename` or `re1:/path/filename`—File on a local Routing Engine.

`routing-instance`—Name of the routing_instance.

`source-address`—Local address to be used in originating the connection.

`terminal`—Use login terminal.

Required Privilege Level

configure—To enter configuration mode.

Sample Output

The following is an example of a save scenario:

Save a File Using Secure Copy Protocol (scp) with 'source-address' and 'routing-instance' options

To save the configuration to a remote system, enter the following save command using `scp` with the `source-address` and `routing-instance` options:

```
root@host# save scp://user@hostname/path/filename routing-instance instance-name source-address
address
```

Release Information

Command introduced before Junos OS Release 7.4.

saved-core-context (System)

IN THIS SECTION

- Syntax | 16320
- Hierarchy Level | 16320
- Description | 16320
- Required Privilege Level | 16321
- Release Information | 16321

Syntax

```
(saved-core-context | no-saved-core-context);
```

Hierarchy Level

```
[edit system]
```

Description

Configure whether the device saves core files generated by internal Junos processes, along with contextual information (system log files and a copy of the current configuration):

- `saved-core-context`—The device saves each core file and its associated context in a compressed tar file named **/var/tmp/*process-name*.core.*core-number*.tgz**.
- `no-saved-core-context`—The router does not save cores files and their associated context.

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

- Hierarchy Level | 16329
- Description | 16329
- Required Privilege Level | 16329
- Release Information | 16329

Syntax

```
scale-mode
```

Hierarchy Level

```
[edit firewall family filter]
```

Description

Programs the filter on a single replication instance instead of the default behavior of programming the filter on two replication instances. Use `scale-mode` to accommodate more firewall filter terms, when the need is to provide more scale than performance.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Evolved Release 24.1

scale-optimized

IN THIS SECTION

- Syntax | 16329
- Hierarchy Level | 16330
- Description | 16330
- Required Privilege Level | 16330
- Release Information | 16331

Syntax

```
scale-optimized;
```

Hierarchy Level

```
[edit firewall family protocol-family-name filter filter-name],
[edit logical-systems logical-system-name firewall family protocol-family-name filter filter-
name]
```

Description

Specify to optimize the interface specific firewall filters in the PFE itself.

When an interface specific firewall filter is configured with multiple Interface bind point instances, the PTX halp software allocates resources for each interface instance separately, and the resources consumption is directly proportional to the number of bind points. This happens because, RE Junos dfw software creates independent instances for each bind point of an interface specific filter.

For example, if an interface specific firewall filter with 'x' number of prefix matches is bound to 'y' number of interfaces (bind points), the Junos software sends 'x' number of independent firewall instances to the PFE software each with 'y' numbers of prefix matches. This automatically consumes 'x * y' numbers of prefixes in the Alpha match block of FLT, and this leads to Alpha block prefix scale issue in FLT. When you add the `scale-optimized` flag under the filter hierarchy, the interface specific firewall filters are optimized in the PFE itself.

The `scale-optimized` flag has the following limitations:

- Can only be configured along with `interface-specific` flag.
- Applicable only to IPv6 and IPv4 families.
- Does not support the `next term` action.
- Does not work with filter lists. Filter lists create unique interface-specific filter for each interface they are applied on. Filters lists do not have a template filter, from which they are copied. It does not add any advantage having scale-optimized flag.
- Cannot be applied to both input and output directions for an interface.
- The `scale-optimized` flag should be configured along with filter configuration. If you add the `scale-optimized` flag to an existing filter configuration, the filter counters do not increase. To resolve the filter counter issue, create a new filter with the `scale-optimized` flag, replace the filter on the interface and commit it.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 18.1.

scan-extension

IN THIS SECTION

- Syntax | 16332
- Hierarchy Level | 16333
- Description | 16333
- Required Privilege Level | 16333
- Release Information | 16333

Syntax

```
scan-extension filename;
```

Hierarchy Level

```
[edit security utm default-configuration]
[edit security utm feature-profile anti-virus kaspersky-lab-engine profile profile-name scan-options]
```

Description

For antivirus file extension scanning, configure the scan extension setting by specifying the name of the defined file extension list.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

The Kaspersky feature is not supported from Junos OS Release 15.1X49-D10 onwards. For previous releases, statement introduced in Junos OS Release 9.5.

The `[edit security utm default-configuration]` hierarchy level is introduced in Junos OS Release 18.2R1.

scan-mode

IN THIS SECTION

- Syntax | 16334
- Hierarchy Level | 16334
- Description | 16334
- Options | 16334
- Required Privilege Level | 16334
- Release Information | 16334

Syntax

```
scan-mode  (all | by-extension);
```

Hierarchy Level

```
[edit security utm default-configuration]
[edit security utm feature-profile anti-virus kaspersky-lab-engine profile profile-name scan-
options]
```

Description

You can scan all content or scan content with specific file extensions. You can use a file extension list to define a set of file extensions that are used in file extension scan mode. The antivirus module can then only scan files with extensions on the scan-extension list.

Options

- `all`—Scan all files.
- `by-extension`—Scan only files with extensions specified in a file extension list custom object.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

The scan-mode is not supported from Junos OS Release 15.1X49-D10 onwards. For previous releases, the statement introduced in Junos OS Release 9.5.

The `[edit security utm default-configuration]` hierarchy level is introduced in Junos OS Release 18.2R1.

Change History Table

Feature support is determined by the platform and release you are using. Use Feature Explorer to determine if a feature is supported on your platform.

Release	Description
15.1X49-D10	The scan-mode is not supported from Junos OS Release 15.1X49-D10 onwards.

Syntax

```
scan-options {
    content-size-limit value;
    decompress-layer-limit value;
    (no-pre-detection | pre-detection);
    timeout value;
    (uri-check|no-uri-check);
}
```

Hierarchy Level

```
[edit security utm default-configuration anti-virus]
```

Description

Configure the antivirus feature to scan specific types of traffic based on various scanning configuration parameters. The scan engine scans the data by accessing the virus pattern database. You can download and uninstall the Avira scan engine. The antivirus module is the software subsystem on the gateway device that scans specific application layer traffic to protect the user from virus attacks and to prevent virus from spreading. The antivirus module software subsystem consists of a virus signature database, an application proxy, the scan manager, and the scan engine. The scan engine requires a valid license

Options

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.5.

The `[edit security utm default-configuration]` hierarchy level is introduced in Junos OS Release 18.2R1.

The `[edit antivirus scan-options]` hierarchy level is deprecated in Junos OS Release 18.2R1.

scheduler scheduler-name;
```

Hierarchy Level

```
[edit class-of-service fabric scheduler-map priority (high | low)]
```

Description

Define scheduler name. For M320, MX Series, T Series routers and for EX Series switches only, specify a scheduler to associate with a fabric queue. For fabric CoS configuration, schedulers are restricted to transmit rates and drop profiles.

Options

scheduler-name—Name of the scheduler configuration block.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Syntax

```
scheduler-map-chassis (derived | map-name);
```

Hierarchy Level

```
[edit class-of-service interfaces interface-type-fpc/pic/*]
```

Description

For IQ and IQ2 interfaces, as well as on the 10x10GE MIC with SFP+, assign a custom scheduler to the packet forwarding component queues that control the aggregated traffic transmitted into the entire PIC.

Default

On Intelligent Queuing (IQ) and Intelligent Queuing 2 (IQ2) interfaces, as well as on the 10x10GE MIC with SFP+, the traffic that is fed from the packet forwarding components into the PIC uses low packet loss priority (PLP) by default and is distributed evenly across the four chassis queues (not PIC queues), regardless of the scheduling configuration for each logical interface. This default behavior can cause traffic congestion.

Options

`derived`—Sets the chassis queues to derive their scheduling configuration from the associated logical interface scheduling configuration.

`map-name`—Name of the scheduler map configured at the `[edit class-of-service scheduler-maps]` hierarchy level.

> **BEST PRACTICE**: It is always preferred that you apply a custom scheduler map instead of using the `derived` option. We strongly recommend that you do *not* use the `derived` option if the PIC is oversubscribed.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

- Hierarchy Level | 16352
- Description | 16352
- Options | 16352
- Required Privilege Level | 16352
- Release Information | 16352

Syntax

```
scheduler-map (map-name);
```

Hierarchy Level

```
[edit dynamic-profiles profile-name class-of-service traffic-control-profiles profile-name]
```

Description

Associate a scheduler map name with a traffic-control profile in a dynamic profile.

The scheduler map can be defined dynamically (at the `[edit dynamic-profiles profile-name class-of-service scheduler-maps]` hierarchy level) or statically (at the `[edit class-of-service scheduler-maps]` hierarchy level).

Options

map-name—Name of the scheduler map or the Junos predefined variable (`$junos-cos-scheduler-map`). When you specify the variable, the scheduler-map name is obtained from the RADIUS server when a subscriber authenticates over the interface to which the dynamic profile is attached.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.3.

The `$junos-cos-scheduler-map` variable introduced in Junos OS Release 9.4.

Security Policies Overview

scheduler (System Security Profile)

IN THIS SECTION

- Syntax | 16366
- Hierarchy Level | 16366
- Description | 16366
- Options | 16367
- Required Privilege Level | 16367
- Release Information | 16367

Syntax

```
scheduler {
    maximum maximum;
    reserved reserved;
}
```

Hierarchy Level

```
[edit system security-profile]
```

Description

Specify the number of schedulers that user logical system administrators and primary logical system administrators can configure for their logical systems if the security profile is bound to the logical systems.

The primary administrator:

- uses security profiles to provision logical systems with resources.
- binds security profiles to user logical systems and the primary logical system.

- can configure more than one security profile, specifying different amounts of resource allocations in various profiles.

Only the primary administrator can create security profiles and bind them to logical systems.

Options

maximum A maximum allowed quota. If a logical system requires more of a resource than its reserved amount allows, it can utilize resources configured for the global maximum amount if they are available—that is, if they are not allocated to other logical systems. The maximum allowed quota specifies the portion of the free global resources that the logical system can use. The maximum allowed quota does not guarantee that the amount specified for the resource in the security profile is available. Logical systems compete for global resources.

- **Range:** 0 through 64

reserved A reserved quota that guarantees that the resource amount specified is always available to the logical system.

- **Default:** 0

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.2.

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

RELATED DOCUMENTATION

Configuring Multicast Snooping

scope-policy

IN THIS SECTION

- Syntax | 16381
- Hierarchy Level | 16381
- Description | 16381
- Options | 16381

Required Privilege Level | 16381
Release Information | 16382

Syntax

```
scope-policy [ policy-names ];
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-options multicast],
[edit routing-options multicast]
```

NOTE: You can configure a scope policy at these two hierarchy levels only. You cannot apply a scope policy to a specific routing instance, because all scoping policies are applied to all routing instances. However, you can apply the **scope** statement to a specific routing instance at the **[edit routing-instances *routing-instance-name* routing-options multicast]** or **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options multicast]** hierarchy level.

Description

Apply policies for scoping. The policy must be correctly configured at the **edit policy-options policy-statement** hierarchy level.

Options

policy-names—Name of one or more multicast scope policies.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

RELATED DOCUMENTATION

scope | 16379

scope (Security IDP Chain Attack)

IN THIS SECTION

- Syntax | 16382
- Hierarchy Level | 16382
- Description | 16382
- Options | 16383
- Required Privilege Level | 16383
- Release Information | 16383

Syntax

```
scope (session | transaction);
```

Hierarchy Level

```
[edit security idp custom-attack attack-name attack-type chain]
```

Description

Specify whether the match should occur over a single session or can be made across multiple transactions within a session.

Options

- `session`—Allow multiple matches for the object within the same session.
- `transaction`—Match the object across multiple transactions that occur within the same session.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.3.

scope (Security IDP Custom Attack)

IN THIS SECTION

- Syntax | 16383
- Hierarchy Level | 16384
- Description | 16384
- Options | 16384
- Required Privilege Level | 16384
- Release Information | 16384

Syntax

```
scope (destination | peer | source);
```

Hierarchy Level

```
[edit security idp custom-attack attack-name time-binding]
```

Description

Specify whether the counting of the attack is from the same source IP address, the same destination IP address, or a peer.

Options

- `destination`—IDP detects attacks to a given destination IP address for the specified number of times, regardless of the source IP address.
- `peer`—IDP detects attacks between source and destination IP addresses of the sessions for the specified number of times.
- `source`—IDP detects attacks from a given source IP address for the specified number of times, regardless of the destination IP address.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.3.

[edit security],
[edit tenants tenant-name security]
```

Description

Configure the security screen options. For every security zone, you can enable a set of predefined screen options that detect and block various kinds of traffic that the device determines as potentially harmful.

Options

ids-options *screen-name*
: Name of the screen configured at the `security screen ids-options` level. Define screens for the intrusion detection service (IDS).

trap
: Configure trap interval. Enable or disable the sending of Simple Network Management Protocol (SNMP) notifications when the state of the connection changes. Traps are

unsolicited messages sent from an SNMP agent to remote network management systems or trap receivers.

`white-list` Set of IP addresses for allowlist. Configure an allowlist of IP addresses that are to be exempt from the SYN cookie and SYN proxy mechanisms that occur during the SYN flood screen protection process. An allowlist contains known trusted IP addresses and URLs. Content downloaded from locations on the allowlist does not have to be inspected for malware.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.5.

The `description` option added in Junos OS Release 12.1.

The `tenant` option is introduced in Junos OS Release 18.3R1.

            }
        }
        nat-only;
        permit (Security SCTP) {
            payload-protocol name;
        }
    }
    traceoptions (Security SCTP) {
        file <filename> <files files> <match match> <size size> <(world-readable | no-world-
readable)>;
        flag name;
        no-remote-trace;
    }
}
```

Hierarchy Level

```
[edit security]
```

Description

Use the Stream Control Transmission Protocol (SCTP) commands to configure SCTP objects, configure SCTP logs, set trace options, and set address rate limit.

From Junos OS Release 20.4R1 onwards, the `[edit security gprs]` hierarchy level is replaced by `[edit security gtp]`.

Options

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.2. Support for the `nat-only` option added in Junos OS Release 12.1X45-D10. Support for the `profile` statement added in Junos OS Release 12.1X46-D10.

SCTP Configuration

sdsl-bytes

IN THIS SECTION

- Syntax | 16399
- Hierarchy Level | 16399
- Description | 16399
- Options | 16399
- Required Privilege Level | 16399
- Release Information | 16399

Syntax

```
sdsl-bytes bytes;
```

Hierarchy Level

```
[edit protocols ancp qos-adjust]
```

Description

Adjust the number of frame overhead bytes by the specified number of bytes in the actual downstream rate reported in the ANCP Port Up message for an SDSL access line. The ANCP agent reports the adjusted value to CoS. The adjusted value accounts for the traffic encapsulation overhead.

> **NOTE**: Starting in Junos OS Release 17.4R1, this statement is deprecated and replaced by the `sdsl-overhead-bytes` option of the `access-line` statement at the `[edit system]` hierarchy level. The ANCP agent ignores the `sdsl-bytes` statement if it is present. This means that when you upgrade from Junos OS Release 17.3 or earlier with an existing configuration, you must reconfigure your adjustment with the `access-line` statement.

Options

bytes Number of bytes added to or subtracted from the actual downstream frame overhead.

- **Range:** -100 through 100 bytes
- **Default:** 0 bytes

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 14.2.

Statement deprecated in Junos OS Release 17.4R1.

Change History Table

Feature support is determined by the platform and release you are using. Use Feature Explorer to determine if a feature is supported on your platform.

Release	Description
17.4R1	Starting in Junos OS Release 17.4R1, this statement is deprecated and replaced by the `sdsl-overhead-bytes` option of the `access-line` statement at the `[edit system]` hierarchy level.

sdsl-overhead-adjust

IN THIS SECTION

- Syntax | 16400
- Hierarchy Level | 16401
- Description | 16401
- Options | 16401
- Required Privilege Level | 16401
- Release Information | 16401

Syntax

```
sdsl-overhead-adjust percentage;
```

Hierarchy Level

```
[edit protocols ancp qos-adjust]
```

Description

Adjust the actual downstream rate for an SDSL access line reported in the ANCP Port Up message by multiplying the rate by the specified percentage. The ANCP agent reports the adjusted rate to CoS.

> **NOTE**: Starting in Junos OS Release 17.4R1, this statement is deprecated and replaced by the `sdsl-overhead-adjust` option of the `access-line` statement at the `[edit system]` hierarchy level. The ANCP agent ignores the `sdsl-overhead-adjust` statement if it is present. This means that when you upgrade from Junos OS Release 17.3 or earlier with an existing configuration, you must reconfigure your adjustment with the `access-line` statement.

Options

percentage Percentage by which to multiply the rate.

- **Range:** 80 through 100 percent
- **Default:** 100 percent

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 14.2.

Statement deprecated in Junos OS Release 17.4R1.

Change History Table

Feature support is determined by the platform and release you are using. Use Feature Explorer to determine if a feature is supported on your platform.

Release	Description
17.4R1	Starting in Junos OS Release 17.4R1, this statement is deprecated and replaced by the `sdsl-overhead-adjust` option of the `access-line` statement at the `[edit system]` hierarchy level.

search

IN THIS SECTION

- Syntax | **16402**
- Hierarchy Level | **16403**
- Description | **16403**
- Options | **16403**
- Required Privilege Level | **16403**
- Release Information | **16403**

Syntax

```
search {
    admin-search {
        distinguished-name distinguished-name;
        password password;
    }
```

```
    search-filter filter-name;
}
```

Hierarchy Level

```
[edit access ldap-options],
[edit access profile profile-name ldap-options]
```

Description

Specify that a search is used to get a user's LDAP distinguished name (DN). The search is performed based on the search filter and the part typed in by the user during authentication.

Options

The remaining statements are explained separately.

Required Privilege Level

access—To view this statement in the configuration.

access-control—To add this statement to the configuration.

Configuring AS or Multiservices PIC Redundancy

secondary connection (Identity Management Advanced Query)

IN THIS SECTION

- Syntax | 16409
- Hierarchy Level | 16410
- Description | 16410
- Options | 16411
- Required Privilege Level | 16411
- Release Information | 16411

Syntax

```
secondary {
    address address;
    ca-profile ca-profile;
    client-id client-id;
    client-secret client-secret;
    interface interface-name;
    routing-instance routing-instance -name;
    source source-address;
}
```

Hierarchy Level

```
[edit services user-identification identity-management connection]
```

Description

Configure parameters that the SRX Series Firewall uses to connect to the Juniper Identity Management Service (JIMS) secondary server and authenticate to it to obtain an access token. JIMS requires that the SRX Series Firewall use OAuth2 to authenticate to it before the SRX Series Firewall can query the JIMS server for user identity information. The SRX Series Firewall must provide the JIMS server with credentials, including a client ID and a client secret. If the client is authenticated-in this case the SRX Series Firewall—it is granted an access token. (See RFC 6749.) Both the client ID and the client secret must be consistent with the API client configured on the JIMS Service primary server.

In addition to configuring the client ID and the client secret, you configure a ca-certificate for the secondary server, if one exists. You configure the file name of the JIMS's ca-certificate. The certificate enables the SRX Series Firewall to verify the identity of JIMS and that it is trusted for the SSL connection.

The SRX Series Firewall always attempts to connect to the primary server first. When one or more queries to the primary server fails, the system falls back to the secondary server.

address- Configure the IP address for the secondary JIMS server. The SRX Series Firewall requires the server IP address to connect to the server to obtain an access code that allows it to query the server for user identity information. The IP address is configured as part of a collection of information which includes the SRX Series Firewall's client ID, client secret, and ca-certificate information.

The SRX Series Firewall uses the secondary server when the primary one fails. You configure the SRX Series Firewall to connect to the primary server separately. This feature supports only IPv4 addresses.

client-id- Client ID that the SRX Series provides to the JIMS Service secondary server as part of its authentication to it. The SRX Series Firewall must authenticate to the server to obtain an access token that allows the SRX Series Firewall to query the server for user identity information The client ID must be consistent with the API client configured on the JIMS primary server.

client-secret- Client secret that the SRX Series provides to the JIMS secondary server as part of its authentication to it. The client secret must be consistent with the API client configured on the JIMS secondary server.

Interface- Client interface name to connect with JIMS server.

routing-instance Client routing instance name to connect with JIMS server. When the client interface connects to JIMS server, routing-instance is auto selected based on the location of interface.

sourceSource address of the request depends on the JIMS server status. If the status is online, then SRX Series Firewall gets source address otherwise the source address is auto selected.

> **WARNING**: Before you use this feature, you must disable active-directory-access and authentication-source options under the user-identification hierarchy. You cannot commit this configuration if active directory authentication or the ClearPass query and webapi functions are configured and committed.

Options

address	IP address of the secondary server.
ca-profile	CA profile name
client-id	Client ID for OAuth2 grant
client-secret	Client secret for OAuth2 grant

Required Privilege Level

1. services—To view this statement in the configuration.
2. services-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 15.1X49-D100.

IPv6 address support introduced in Junos OS Release 18.3R1.

Source, interface, and routing-instance options are introduced in Junos OS Release 21.1R1.

Option ca-profile introduced in Junos OS Release 23.2R1.

secondary-interface (Aggregated Inline Services)

IN THIS SECTION

- Syntax | 16413
- Hierarchy Level | 16413
- Description | 16413
- Options | 16414
- Required Privilege Level | 16414
- Release Information | 16414

Syntax

```
secondary-interface interface-name;
```

Hierarchy Level

```
[edit interfaces asix aggregated-inline-services-options]
```

Description

Specify the secondary (backup) inline services member link in the asi bundle. You must also configure a primary (active) member link on a different MPC with the `primary-interface` statement. The secondary

member provides 1:1 redundancy for subscriber service sessions on the primary member link. The bandwidth configured at the `[edit chassis fpc slot pic number inline-services bandwidth]` hierarchy level must be the same for both member links.

Redundancy is not achievable if you configure the primary and secondary interface on the same MPC, because both member interfaces go down if the card goes down. Consequently, if you configure both interfaces on the same MPC, the subsequent configuration commit fails.

Options

interface-name	Name of an inline services physical interface.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 16.2.

- Release Information | 16420

Syntax

```
secondary-vtep-address anycast IP address;
```

Hierarchy Level

```
[edit dynamic-profiles name protocols pim],
[edit logical-systems name protocols pim],
[edit logical-systems name routing-instances name protocols pim],
[edit logical-systems name tenants name routing-instances name protocols pim],
[edit protocols pim],
[edit routing-instances name protocols pim],
```

```
[edit tenants name routing-instances name protocols pim]
```

Description

The secondary Virtual Tunnel End Point (VTEP) address.

The *anycast IP address* must match the address under `set routing-instances instance name vtep-source-interface inet evpn-mpls-encap vxlan-source-ip` ***address***.

In earlier versions of Junos, the *anycast IP address* was used by PIM as the primary address to build the VTEP. Starting in Junos OS Release 22.2R1, the *anycast IP address* is not considered the primary address, therefore the `secondary-vtep-address` is necessary for the formation of the VTEP.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

secure-channel

IN THIS SECTION

- Syntax | 16435
- Hierarchy Level | 16435
- Description | 16435
- Options | 16436
- Required Privilege Level | 16436
- Release Information | 16436

Syntax

```
secure-channel secure-channel-name {
    direction (inbound | outbound);
    encryption;
    id {
        mac-address mac-address;
        port-id port-id-number;
    }
    offset (0|30|50);
    security-association security-association-number {
        key key-string;
    }
}
```

Hierarchy Level

```
[edit security macsec connectivity-association connectivity-association-name]
```

Description

Create and configure a secure channel to enable and configure MACsec when MACsec is enabled using static secure association key (SAK) security mode.

You do not need to use this option to enable MACsec using static connectivity association key (CAK) security mode. All configuration for MACsec using static CAK security mode is done inside of the connectivity association but outside of the secure channel. When MACsec is enabled using static CAK security mode, an inbound and an outbound secure channel—neither of which is user-configurable—is automatically created within the connectivity association.

Options

The remaining statements are explained separately.

Syntax

```
secure-neighbor-discovery {
    command binary-file-path;
    disable;
    failover (alternate-media | other-routing-engine);
}
```

Hierarchy Level

```
[edit system processes]
```

Description

Provide support for protecting Secure Neighbor Discovery Protocol (SEND) messages.

Options

- `command` *`binary-file-path`*—Path to the binary process.
- `disable`—Disable the Secure Neighbor Discovery (SEND) protocol process.
- `failover`—Configure the device to reboot if the software process fails four times within 30 seconds, and specify the software to use during the reboot.
  - `alternate-media`—Configure the device to switch to backup media that contains a version of the system if a software process fails repeatedly.
  - `other-routing-engine`—Instruct the secondary Routing Engine to take the primary role if a software process fails. If this statement is configured for a process, and that process fails four times within 30 seconds, then the device reboots from the secondary Routing Engine.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

secure-proxy

IN THIS SECTION

- Syntax | 16441
- Hierarchy Level | 16441
- Description | 16441
- Options | 16442
- Required Privilege Level | 16442
- Release Information | 16442

Syntax

```
secure-proxy {
    profile name {
        drop-on-dns-error;
        dynamic-web-application;
        dynamic-web-application-group;
        proxy-address name {
            ip ip-address;
            port port-number;
        }
    }
}
```

Hierarchy Level

```
[edit services web-proxy]
```

Description

Configure secure Web proxy profile.

When you configure secure Web proxy on SRX Series Firewall, it intercepts the session and allows sessions that are interested in specific application and are destined to a configured external web-proxy. The device connects sessions directly to the Web server bypassing the external proxy server. Connections that do not match the applications are routed to the external proxy server.

Since the Secure Web proxy forwards traffic based on applications either to the external proxy server or to the Web server, you can define the routing behavior based on applications. For example, you can specify Office 365 application group in secure Web proxy profile to bypass the external proxy server for connections to Office 365.

To configure secure Web proxy on the SRX Series Firewall, you must define a Web proxy profile by specifying external proxy server details and dynamic application. You can associate this secure Web proxy profile with security policy. The secure Web profile is applied on the traffic matching the application and security policy. The session is now allowed to bypass the external proxy server and connect to the Web server directly.

Options

profile *name*	Name of the secure Web proxy profile.
drop-on-dns-error	Drop the Web proxy session on DNS error.
dynamic-web-application	Dynamic web application.
dynamic-web-application-group	Dynamic web application group.
proxy-address *name*	Name of the external proxy server.
ip *ip-address*	IP address of the external proxy server.
port *port-number*	Port number of the external proxy server.

secured-port-block-allocation

IN THIS SECTION

- Syntax | 16445
- Hierarchy Level | 16445
- Description | 16445
- Options | 16446
- Required Privilege Level | 16446
- Release Information | 16446

Syntax

```
secured-port-block-allocation {
    active-block-timeout timeout-seconds;
    block-size block-size;
    max-blocks-per-address max-blocks;
}
```

Hierarchy Level

```
[edit services nat pool pool-name port]
```

Description

When you use block allocation, one or more blocks of ports in a NAT pool address range are available for assignment to a subscriber.

Port block allocation is supported on MX series routers with MS-DPCs and on M Series routers with MS-100, MS-400, and MS-500 MultiServices PICS. Port block allocation is supported on MX series routers with MS-MPCs and MS-MICs starting in Junos OS release 14.2R2.

NOTE: If you define the session lifetime globally for a Multiservices (`ms`-) interface (by using the `session-timeout seconds` statement at the `[edit interfaces interface-name services-options]` hierarchy level), the session is terminated even if traffic continues to flow beyond that time period. When continuous traffic transmission occurs, the session is reset immediately after the timeout period. When you configure the same value for the session timeout and the active port block allocation timeout, the system might not determine that the active port block timeout period has elapsed. As a result, when the active port block timeout elapses, the system might use the same block for the initial port allocation that was used previously. However, for the subsequent allocation of a port block, the system identifies the active block timeout value correctly and allocates a port from a new block. This behavior is expected when the session timeout and port block timeout values are identical. To avoid this problem, we recommend that you configure different values for session timeout and port block timeout so that the `JSERVICES_NAT_PORT_BLOCK_ALLOC` system logging message is generated at correct intervals of the active port block timeout value.

> **NOTE**: If you make any configuration changes to a NAT pool that has secured port block allocation configured, you must delete the existing NAT address pool, wait at least 5 seconds, and then configure a new NAT address pool. We also strongly recommend that you perform this procedure if you make any changes to the NAT pool configuration, even when secured port block allocation is not configured.

Options

active-block-timeout *timeout-seconds*

Interval, in seconds, during which a block is active. After the timeout elapses, a new block is allocated, even if ports are available in the active block.

- **Range:** 0 through 86400. When you specify 0, the active block transitions to inactive only when it runs out of ports and a new block is allocated. Any inactive block without any ports in use will be freed to the NAT pool, unless it is active block. The range is 1 through 512.
- **Default:** 120

block-size *block-size*

Number of ports included in a block.

- **Range:** For the Multiservices DPC only, 1 through 32,000
- **Range:** For the Multiservices MPC and Multiservices MIC only, 1 through the total number of configured ports. For example, for a port range of 1024 through 61,024, the block-size range is 1 through 60,000.
- **Default:** 128

max-blocks-per-address *max-blocks*

Maximum number of blocks that can be allocated to a user address. The range is 1 through 512.

security-association (MACSec)

IN THIS SECTION

- Syntax | 16451
- Hierarchy Level | 16451
- Description | 16451
- Default | 16451
- Options | 16451
- Required Privilege Level | 16452
- Release Information | 16452

Syntax

```
security-association security-association-number {
    key key-string;
}
```

Hierarchy Level

```
[edit security macsec connectivity-association connectivity-association-name secure-channel
secure-channel-name]
```

Description

Specifies the number of one of the security associations in the secure channel when MACsec is enabled using static secure association key (SAK) security mode. Because SAKs are created by the key server when MACsec is enabled using static connectivity association key (CAK) security mode, the `security-association` statement is not used when enabling MACsec using static CAK security mode.

You must configure at least two security associations to enable MACsec using static SAK security mode. MACsec initially establishes a secure connection when a security association number and key match on both ends of an Ethernet link. After a certain number of Ethernet frames are securely transmitted across the Ethernet link, MACsec automatically rotates to a new security association with a new security association number and key to maintain the secured Ethernet link. This rotation continues each time a certain number of Ethernet frames are securely transmitted across the secured Ethernet link, so you must always configure MACsec to have at least two security associations.

Default

No security keys are configured, by default.

Options

security-association-number

Specifies the security association number and creates the SAK.

The security association number is a whole number between 0 and 3. You can configure two security associations in a secure channel when enabling MACsec using static security keys.

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 15.1.

        }
    }
    mode transport;
}
```

Hierarchy Level

```
[edit security ipsec]
```

Description

Configure a manual IPsec security association (SA) to be applied to an OSPF or OSPFv3 interface or virtual link. IPsec can provide authentication and confidentiality to OSPF or OSPFv3 routing packets.

Options

sa-name Name of the SA.

description Specify a text description for the SA.

direction Direction of the manual SA. For this feature, the direction must be `bidirectional`. Decrypt and authenticate the incoming and outgoing traffic using the same algorithm, keys, or SPI in both directions, unlike inbound and outbound SAs that use different attributes in both directions.

- **Values:** `algorithm`—Hash algorithm that authenticates packet data. It can be one of the following:
  - `hmac-md5-96`—Produces a 128-bit digest. This is the default.
  - `hmac-sha1-96`—Produces a 160-bit digest.

- `hmac-sha-256`—Produces a 256-bit digest.
- `hmac-sha-384`—Produces a 384-bit digest.
- `hmac-sha-512`—Produces a 512-bit digest.

Starting in Junos OS Release 22.2R1, MX240, MX480, and MX960 with MX-SPC3, SRX Series Firewalls and vSRX Virtual Firewall running iked process supports all the listed authentication algorithms.

`key`—Type of authentication key. It can be one of the following:

- `ascii-text` *key*—ASCII text key. For `hmac-md5-96`, the key is 16 ASCII characters; for `hmac-sha1-96`, the key is 20 ASCII characters.
- `hexadecimal` *key*—Hexadecimal key. For `hmac-md5-96`, the key is 32 hexadecimal characters; for `hmac-sha1-96`, the key is 40 hexadecimal characters.

- **Values:** `encryption`—Configure an encryption algorithm and key for a manual Security Association (SA). It can be one of the following:
  - `algorithm`—Select the encryption algorithm for the internal Routing-Engine-to-Routing-Engine IPsec security association (SA) configuration.
    - `des-cbc`—Encryption algorithm with block size of 8 bytes (64 bits) and key size 48 bits.
    - `3des-cbc`—Encryption algorithm with block size of 8 bytes (64 bits) and key size of 192 bits.

      For `3des-cbc`, we recommend that the first 8 bytes be different from the second 8 bytes, and the second 8 bytes be the same as the third 8 bytes.
    - `aes-128-cbc`—Advanced encryption algorithm that has a key size of 16 bytes; its key size is 128 bits long.
    - `aes-192-cbc`—Advanced encryption algorithm that has a key size of 24 bytes; its key size is 192 bits long.
    - `aes-256-cbc`—Advanced encryption algorithm that has a key size of 32 bytes; its key size is 256 bits long.

    Starting in Junos OS Release 22.2R1, MX240, MX480, and MX960 with MX-SPC3, SRX Series Firewalls and vSRX Virtual Firewall running iked process supports all the listed encryption algorithms.

- `key`—Type of encryption key. It can be one of the following:
  - `ascii-text key`—ASCII text key. For the `des-cbc` option, the key contains 8 ASCII characters; for `3des-cbc`, the key contains 24 ASCII characters.
  - `hexadecimal key`—Hexadecimal key. For the `des-cbc` option, the key contains 16 hexadecimal characters; for the `3des-cbc` option, the key contains 48 hexadecimal characters.

protocol Define the IPsec protocol for a manual security association (SA). The protocol can be one of the following:

- `ah`—Authentication Header protocol. If you configure AH protocol, it is mandatory to configure the authentication algorithm and the key.
- `esp`—Encapsulating Security Payload (ESP) protocol. This is the default.

  If you configure ESP protocol, it is mandatory to configure either authentication algorithm or encryption algorithm or both. If you did not configure ESP protocol and did not configure either authentication or encryption algorithm, then we do not provide authentication or encryption support.

spi *spi-value* Configure the security parameter index (SPI) for a security association (SA). An arbitrary value that uniquely identifies which SA to use at the receiving host (the destination address in the packet).

- **Range:** 256 through 16,639

mode SA mode. For this feature, the mode must be `transport`.

Required Privilege Level

view-level—To view this statement in the configuration.

control-level—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.1X46-D20.

Authentication algorithm configuration options, hmac-md5-96, hmac-sha1-96, hmac-sha-256, hmac-sha-384, and hmac-sha-512 are added in Junos OS Release 22.2R1 for MX240, MX480, and MX960 with MX-SPC3, SRX Series Firewalls and vSRX Virtual Firewall running iked process.

Encryption algorithm configuration options, des-cbc, 3des-cbc, aes-128-cbc, aes-192-cbc, and aes-256-cbc are added in Junos OS Release 22.2R1 for MX240, MX480, and MX960 with MX-SPC3, SRX Series Firewalls and vSRX Virtual Firewall running iked process.

```

Description

You can configure security intelligence profiles and policies to work with security intelligence feeds, such as infected hosts and C&C. You then configure a firewall policy to include the security intelligence policy, for example, block outgoing requests to a C&C host.

Options

authentication Configure authentication, such as an auth token or TLS profile, to commute with the feed server. This operation is performed by the ops script used to enroll your devices and is typically not required afterwards. If you have problems establishing a connection with the Juniper ATP Cloud cloud server, we recommend that you rerun the ops script instead of manually entering all the CLI commands.

traceoptions Set security intelligence trace options.

- file—Name of the file to receive the output of the tracing operation.
  - `files` *`number`* —Maximum number of trace files

    Range: 2 through 1000
  - match— Regular expression for lines to be logged
  - no-world-readable—Prevent any user from reading the log file
  - size—Maximum size of each trace file

    Range: 10240 through 1073741824
  - world-readable—Allow any user to read the log file
- flag—Tracing operation to perform
  - all—All interface tracing operation
  - feed—Trace feed operation
  - ipc—Trace interface interprocess communication (IPC) module messages
- level—Level of debugging output
- no-remote-trace—Disable the remote trace

url *url-address* Configure the URL of the feed server. This operation is performed by the ops script used to enroll your devices and is typically not required afterwards. If you have problems establishing a connection with the Juniper ATP Cloud cloud server, we recommend that you rerun the ops script instead of manually entering all the CLI commands.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 19.3R2 on MX Series routers with Juniper Juniper Advanced Threat Prevention Cloud (ATP).

Support added in Junos OS Release 19.3R2 for Next Gen Services on MX Series routers MX240, MX480, and MX960. This support runs inline on the MPC card.

```

```
[edit security policies from-zone zone-name to-zone zone-name policy policy-name then reject
application-services]
```

Description

Starting in Junos OS Release 20.2R1, you can add source and destination addresses to the security intelligence (SecIntel) profiles to generate security feeds in a security policy by configuring the `security-intelligence` command. After the feeds are generated, you can configure other security policies to use the feeds as a `dynamic-address` to match designated traffic and perform policy actions.

Options

add-destination-ip-to-feed Add the destination IP address to thesecurity feed.

add-source-ip-to-feed Add the source IP address to the security feed.

The feed-name must be predefined and installed by SecIntel with the feed type and a specific ID.

Required Privilege Level

security—To view this statement in the configuration.

```

Description

Define the threat level and action for the Web filter profile. The packets are redirected at the Packet Forwarding Engine based on the configured threat-level action associated with the threat-level of the destination IP address.

Options

threat-level Define the Web filtering threat level. The value ranges from 1 through 10

policy-map Map the threat level to a user-attribute defined by the url-filterd.

threat-action Define the way the Packet Forwarding Engine processes packets in response to a threat. Only one action can be configured for each threat level that is defined. The default threat-action is `accept`.

- `drop`—Drop the packets and do not generate a log message.
- `drop-and-log`—Drop the packets and generate a log message.
- `drop-and-sample`—Drop and sample the packets.
- `drop-log-and-sample`—Drop and sample the packets, and generate a log message.
- `log`—Allow the packets and generate a log message.
- `log-and-sample`—Allow, sample the packets, and generate a log message.
- `sample`—Sample the packets.

white-list Allow the IP addresses configured either as a file or as an IP address-list .

black-list Block the IP addresses configured either as a file or as an IP address-list .

```

Description

Using this command, you can configure security intelligence profiles and policies to work with security intelligence feeds, such as infected hosts and C&C. You then configure a firewall policy to include the security intelligence policy, for example, block outgoing requests to a C&C host.

A security intelligence rule can have multiple feed names (`feed-name`) with multiple threat levels. Specifying the threat level is required, but `feed-name` is optional. Juniper ATP Cloud makes sure there is no duplicate feed-name associated with threat levels configured in the same profile. Juniper ATP Cloud uses the following approach:

- If `feed-name` is configured, it looks up the feed-name first.
- If no `feed-name` configured or the `feed-name` is not match, it uses the threat level rules.
- If no rules are present or match, the profile's default rule is used.

Options

authentication

Configure authentication, such as an auth token or TLS profile, to commute with the feed server. This operation is performed by the ops script used to enroll your devices and is typically not required afterwards. If you have problems establishing a connection with the Juniper ATP cloud server, it is recommended that you rerun the ops script instead of manually entering all the CLI commands.

category (all | *category-name*)

Category to be disabled. You can disable a specific category or all. This option is used for temporarily disabling a category during debugging phases.

disable-global-feed (all | feed-name (CC_IP |CC_URL))

Disable the Juniper C&C and URL feed to free the resources on SRX Series Firewalls. The resources are then available for loading custom feeds. The available options are all, CC_IP or CC_URL.

- all—Applies to all feeds.
- CC_IP—Applies to global CC IP feed.
- CC_URL—Applies to global CC URL feed.

policy*policy-name category-profile-name*

Configure the security intelligence policy. You specify the category (such as `CC`) and the security intelligence profile to associate with this policy.

profile *profile-name category* rule *rule-name* (match | then)

Configure security intelligence profile. You specify the profile name, the category (such as CC), and any rules and actions. The actions that you can perform are listed below:

- block—Block with close or drop action
- permit—Permit action
- recommended— Recommended action from feed server
- sinkhole—DNS sinkhole action for malicious DNS queries

> **NOTE**: The action `sinkhole` must be configured only for DNS profile category.

traceoptions

Set security intelligence trace options.

url *url-address*

Configure the URL of the feed server. This operation is performed by the ops script used to enroll your devices and is typically not required afterwards. If you have problems establishing a connection with the Juniper ATP Cloud server, it is

recommended that you rerun the ops script instead of manually entering all the CLI commands.

url-parameter *url-parameter*

This is an internal option. Do not use this option unless instructed to by Juniper Networks Technical Support.

block close infected host file message| redirect-URL

Provides HTTP URL redirection based on infected hosts with the block action.

This allows for administrator notification of Infected Hosts. During the processing of a session IP address, if the IP address is on the infected hosts list and HTTP traffic is using ports 80 or 8080, infected hosts HTTP redirection can be done. If HTTP traffic is using dynamic ports, HTTP traffic redirection cannot be done.

set services security-intelligence profile secintel_profile rule

This example performs feed name-based URL redirection.

```
user@host# set services security-intelligence profile secintel_profile rule secintel_rule1 match
feed-name custom_feed1
uuser@host# set services security-intelligence profile secintel_profile rule secintel_rule1
match threat-level 7
user@host# set services security-intelligence profile secintel_profile rule secintel_rule1 match
threat-level 8
user@host# set services security-intelligence profile secintel_profile rule secintel_rule1 match
threat-level 9
user@host# set services security-intelligence profile secintel_profile rule secintel_rule1 match
threat-level 10
user@host# set services security-intelligence profile secintel_profile rule secintel_rule1 then
action block close http redirect-url http://www.test.com/url1.html

user@host# set services security-intelligence profile secintel_profile rule secintel_rule2 match
feed-name custom_feed2
uuser@host# set services security-intelligence profile secintel_profile rule secintel_rule2
match threat-level 7
user@host# set services security-intelligence profile secintel_profile rule secintel_rule2 match
threat-level 8
user@host# set services security-intelligence profile secintel_profile rule secintel_rule2 match
threat-level 9
user@host# set services security-intelligence profile secintel_profile rule secintel_rule2 match
threat-level 10
user@host# set services security-intelligence profile secintel_profile rule secintel_rule2 then
```

```
action block close http redirect-url http://www.test.com/url2.html
```

set services security-intelligence profile

```
user@host# set services security-intelligence profile cc_profile category CC
```

set services security-intelligence profile

This example configures a profile name, a profile rule and the threat level scores. Anything that matches these scores is considered malware or an infected host.

```
user@host# set services security-intelligence profile cc_profile rule CC_rule match threat-level
[8 9 10]
```

set services advanced-anti-malware connection authentication

This example defines the TLS profile, typically done by the ops script when enrolling devices.

```
user@host# set services advanced-anti-malware connection authentication tls-profile aamw-ssl
```

set services security-intelligence url

This example defines the feed server URL, typically done by the ops script when enrolling devices.

```
user@host# set services security-intelligence url https://cloudfeeds.argon.junipersecurity.net/
api/manifest.xml
```

set services security-intelligence profile secintel_profile rule secintel_rule2 then action block close infected host|http redirect-url http://www.test.com/url2.html

User notification of infected hosts—(Starting in Junos 18.1R1) This command allows you to configure HTTP URL redirection based on infected hosts with the block action. During the processing of a session IP address, if the IP address is on the infected hosts list and HTTP traffic is using ports 80 or 8080, infected hosts HTTP redirection to a specified URL can be used in conjunction with the block action. This allows administrators to receive a notification of the block action. Note that if HTTP traffic is using dynamic ports, HTTP traffic redirection cannot be done

The syntax for the command is as follows:

Syntax: set services security-intelligence profile <name> then action block close <file message|redirect-URL>

For example:

```
user@host# set services security-intelligence profile secintel_profile rule secintel_rule2 then
action block close infected host|http redirect-url http://www.test.com/url2.html
```

To view the HTTP URL redirection counter, type **show services security-intelligence statistics**

set services security-intelligence disable-global-feed all

This example disables the global feed in all SecIntel configurations.

```
user@host# set services security-intelligence disable-global-feed all
```

set services security-intelligence disable-global-feed feed-name CC_IP

This example disables the global CC IP feeds in SecIntel configurations.

```
user@host# set services security-intelligence disable-global-feed feed-name CC_IP
```

set services security-intelligence disable-global-feed feed-name CC_URL

This example disables the global CC URL feeds in SecIntel configurations.

```
user@host# set services security-intelligence disable-global-feed feed-name CC_URL
```

All the security intelligence services are enabled by default. To disable the services, you must use the configuration commands:

- **set services security-intelligence category category-name GeoIP disable**

  This example disables the GeoIP feeds in SecIntel configurations.

  ```
  user@host# set services security-intelligence category category-name GeoIP disable
  ```

- **set services security-intelligence category category-name Whitelist disable**

This example disables allowlist category in SecIntel configurations.

```
user@host# set services security-intelligence category category-name Whitelist disable
```

- **set services security-intelligence category category-name Blacklist disable**

  This example disables blocklist category in SecIntel configurations.

```
user@host# set services security-intelligence category category-name Blacklist disable
```

- **set services security-intelligence category category-name IPFilter disable**

  This example disables IPFilter category in SecIntel configurations.

```
user@host# set services security-intelligence category category-name IPFilter disable
```

Use the `show services security-intelligence` CLI command to verify your settings. Your output should look similar to the following:

```
[edit]
user@host# show services security-intelligence
category {
    category-name {
        Whitelist {
            disable;
        }
        IPFilter {
            disable;
        }
        GeoIP {
            disable;
        }
        Blacklist {
            disable;
        }
    }
}
policy p1 {
```

```
    IPFilter; ## Warning: missing mandatory statement(s): <profile-name>
}
```

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Command introduced in Junos OS 12.1X46. Starting with Junos OS 15.1X49-D110, this command adds the `feed-name` option which can be used in security intelligence rules. Prior to Junos OS 15.1X49-D100 you could perform HTTP URL redirect based on threat levels. With `feed-name`, you can now perform HTTP URL redirection based on a feed name.

User notification of infected hosts—As of Junos OS 18.1R1, there is support HTTP URL redirection based on infected hosts with the block action. This allows for administrator notification of Infected Hosts. During the processing of a session IP address, if the IP address is on the infected hosts list and HTTP traffic is using ports 80 or 8080, infected hosts HTTP redirection can be done. If HTTP traffic is using dynamic ports, HTTP traffic redirection cannot be done. See command at bottom of this page.

The `disable-global-feed` option is introduced in Junos OS Release 20.1R1.

The `DNS` option is introduced in Junos OS Release 20.4R1.

The `Reverse-Shell` category is introduced in Junos OS Release 23.3 R1.

- Options | 16482
- Required Privilege Level | 16482
- Release Information | 16482

Syntax

```
security-level (authentication | none | privacy) {
    notify-view view-name;
    read-view view-name;
    write-view view-name;
}
```

Hierarchy Level

```
[edit snmp v3 vacm access group group-name (default-context-prefix | context-prefix context-prefix) security-model (any | usm | v1 | v2c)]
```

Description

Define the security level used for access privileges.

Default

`none`

Options

`authentication`—Provide authentication but no encryption.

`none`—No authentication and no encryption.

`privacy`—Provide authentication and encryption.

Required Privilege Level

snmp—To view this statement in the configuration.

snmp-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Configure security metadata streaming policy on SRX Series Firewalls to send the metadata and connection patterns of a network traffic to Juniper Networks ATP Cloud for encrypted traffic insights. After configuring the security metadata streaming policy, attach it to the security policy at zone-level.

`set security policies from-zone` *`from-zone`* `to-zone` *`to-zone`* `application-services security-metadata-streaming-policy` *`dns-policy`*

Options

dns-cache Configure a list of static benign and command-and-control (C2) domains in the Domain Name System (DNS) cache to take immediate action on configured domains. Only wildcard domains are allowed. The domain format must be `*.domain_name.domain_ending` . The entries configured in DNS Cache via CLI will remain in the DNS Cache until that configuration is deleted from the device. You can configure a maximum of 500 domains each in benign list and c2 list.

- By default, the action for traffic originating from a benign (allowlisted) domain is `permit`.
- The action for traffic originating from a C2 (blocklisted) domain is based on the action configured under DNS detections.

policy ***policy-name*** Configure the security-metadata-streaming policy.

dns Configure DNS options.

cache Store DNS in cache till time-to-live (TTL). The TTL provided by SRX Series Firewall overrides Juniper ATP Cloud provided TTL.

> **NOTE**: You must configure at least one DNS detection method to configure DNS cache.

- benign—(Optional) Set benign TTL value. The range is 60 to 172800 seconds. Default value is 86400.
- c2—(Optional) Set C2 TTL value. The range is 60 to 172800 seconds. Default value is 86400.

detections Configure the detection type for DNS requests. The available options are all, dga, and tunneling. You can configure any of the following detections.

- all detections
- both dga and tunneling detection
- either dga or tunneling detection

You cannot configure all detections and custom detections(dga and/or tunneling) together. The detections are mutually exclusive.

> **NOTE**: Each detection method has a fallback option which is used in case nothing is detected within a certain number of packets (in case of tunneling) or within a certain time period (in case of DGA).

all Configure all detections.

- action—Specify the action the SRX device will take when a detection is made. The available options are `deny`, `permit`, or `sinkhole`.
- fallback-options—Fallback options for DNS detections. The fallback action is triggered when DNS-based attacks are not detected (DGA verdict is not received within 100ms (default value of verdict-timeout) and DNS tunnel is not detected within 4 packets (default value of inspection-depth)). The available option is to `Log` the DNS requests.
- notification—Global notification action taken for DNS detection methods. The available options are:
  - log—Generates log for DNS requests and DNS detections.
  - log-detections—(recommended) Generates log only for malicious DNS detections.
- verdict-timeout—(Not configurable) Time to wait for a DGA verdict on DNS packet (milliseconds). Default timeout is 100ms for all detections.
- inspection-depth—(Not configurable) Number of packets to be inspected for tunnel detection. Default is 4 packets for all detections.

dga Configure to detect DGA-based attacks on DNS packets.

- action—Specify the action the SRX device will take when a detection is made. The available options are `deny`, `permit`, or `sinkhole`.
- fallback-options—Fallback options for DNS DGA detection. The fallback options are triggered if DGA verdict is not received from Juniper ATP Cloud within the verdict-timeout configured value. The available option is to log the DNS request.
- notification— Notification action taken for DNS DGA detection. The available options are:

- log—Generates log per DNS request and DNS detections.
- log-detections—(recommended) Generates log only for malicious DNS detections.

- verdict-timeout—(Optional) Time to wait for a verdict on DNS Packet (milliseconds). The range is 50 to 500. Default timeout is 100ms.

tunneling Configure to detect DNS tunneling.

- action—Specify the action the SRX device will take when a detection is made. The available options are `deny` (drops tunnel session), `permit` (permits tunnel session), or `sinkhole` (drops the tunnel session and sinkholes the domain).
- fallback-options—Fallback options for DNS tunneling detection. The fallback options are triggered if a tunnel is not detected within the specified number of packets (inspections-depth). The available option is to log the DNS request.
- inspection-depth—(Optional) Number of packets to be inspected for tunnel detection. The range is 0 to 10. Default is 4 packets. 0 indicates forever.
- notification—Notification action taken for DNS tunneling detection. The available options are:
  - log—Generates log per DNS request and DNS detections.
  - log-detections—(recommended) Generates log only for malicious DNS detections.

dynamic-filter Configure dynamic filtering options for security metadata streaming policy on SRX Series Firewalls.

http Configure HTTP options.

- detections—Configure the detection type for HTTP requests. The available options are all and encryptedc2. You can configure any of the following detections:
  - all detections—All detections can only be configured if no other detection is configured.
  - encryptedc2—Encryptedc2 can be configured to detect Command and Control (C&C) communication.
- action—Defines the action taken on the traffic. The default action is permit.
- notification—Defines the notification action taken for the traffic. The available options are:
  - log—Generates log per HTTP request and detections.

- log-detections—(recommended) Generates log only for malicious detections.

- fallback-options—Fallback options for HTTP traffic. The fallback options are triggered if HTTP traffic is not detected. The available option is to log the security metadata streaming actions.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

security-mode (SRX)

IN THIS SECTION

- Syntax | 16493
- Hierarchy Level | 16493
- Description | 16493
- Options | 16493
- Required Privilege Level | 16494
- Release Information | 16494

Syntax

```
security-mode (dynamic | static-cak | static-sak);
```

Hierarchy Level

```
[edit security macsec connectivity-association]
```

Description

Configure the MACsec security mode for the connectivity association.

We recommend enabling MACsec on switch-to-switch Ethernet links using static connectivity association key (CAK) security mode. Static CAK security mode ensures security by frequently refreshing to a new random secure association key (SAK) and by only sharing the SAK between the two devices on the MACsec-secured point-to-point link. Additionally, some optional MACsec features—replay protection, SCI tagging, and the ability to exclude traffic from MACsec—are only available when you enable MACsec using static CAK security mode.

Options

security-mode Specifies the MACsec security mode. Options include:

- `dynamic`—Dynamic mode.

  Dynamic security mode is used to enable MACsec on switch-to-host Ethernet links. In dynamic mode, a master key is retrieved from a RADIUS server by a switch and a host as part of the AAA handshake in separate transactions. The MKA protocol is enabled when the master key is exchanged between the switch and the host.

- `static-cak` —Static connectivity association key (CAK) mode.

  Static CAK security mode is used to enable MACsec on switch-to-switch Ethernet links. In `static-cak` mode, the switch at one end of the point-to-point link acts as the key server and regularly transmits a randomized key using a process that does not transmit any traffic outside of the MACsec-secured point-to-point link.

- `static-sak` —Static secure association key (SAK) mode.

Static SAK security mode is used to enable MACsec on switch-to-switch Ethernet links. In static-sak mode, one of two user-configured security keys is used to secure the point-to-point link. The two security keys are regularly rotated.

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Syntax

```
security-mode security-mode;
```

Hierarchy Level

```
[edit security macsec connectivity-association connectivity-association-name]
```

Description

Configure the MACsec security mode for the connectivity association.

To enable MACsec on a switch-to-host link, you must use dynamic connectivity association key (CAK) mode. For links that connect switches or routers—switch-to-switch, switch-to-router, or router-to-router—you can use static CAK mode or dynamic CAK mode.

NOTE: Dynamic CAK mode is not supported on logical interfaces.

Options

security-mode Specifies the MACsec security mode. Options include:

- `dynamic`—Dynamic CAK mode.

  You can use dynamic CAK mode on switch-to-host links as well as links that connect switches or routers. Dynamic CAK mode relies on 802.1X authentication with EAP-TLS. Public key infrastructure is also required for certificate validation.

- `static-cak`—Static CAK mode.

  You can use static CAK mode on links that connect switching devices. In `static-cak` mode, the CAK must be manually configured on both peer nodes of the point-to-point MACsec link.

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 13.2X50-D15.

The `dynamic` security mode option was introduced in Junos OS Release 14.1X53-D10.

```

Description

Associate a community string with the security name of a user. The community string, which is used for SNMPv1 and SNMPv2c clients in an SNMPv3 system, is configured at the `[edit snmp v3 snmp-community community-index]` hierarchy level.

Options

security-name—Name that is used for messaging security and user access control.

> **NOTE**: The security name must match the configured security name at the `[edit snmp v3 target-parameters target-parameters-name parameters]` hierarchy level when you configure traps or informs.

Required Privilege Level

snmp—To view this statement in the configuration.

snmp-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

security-name (Security Group)

IN THIS SECTION

- Syntax | 16502
- Hierarchy Level | 16502
- Description | 16502
- Options | 16502
- Required Privilege Level | 16502
- Release Information | 16502

Syntax

```
security-name security-name {
    group group-name;
}
```

Hierarchy Level

```
[edit snmp v3 vacm security-to-group security-model (usm | v1 | v2c)]
```

Description

Associate a group or a community string with a configured security group.

Options

security-name—Username configured at the `[edit snmp v3 usm local-engine user username]` hierarchy level. For SNMPv1 and SNMPv2c, the security name is the community string configured at the `[edit snmp v3 snmp-community community-index]` hierarchy level.

Required Privilege Level

snmp—To view this statement in the configuration.

snmp-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

security-name (SNMP Notifications)

IN THIS SECTION

- Syntax | 16503
- Hierarchy Level | 16503
- Description | 16503
- Options | 16503
- Required Privilege Level | 16504
- Release Information | 16504

Syntax

```
security-name security-name;
```

Hierarchy Level

```
[edit snmp v3 target-parameters target-parameters-name parameters]
```

Description

Configure the security name used when generating SNMP notifications.

Options

security-name—If the SNMPv3 USM security model is used, identify the user when generating the SNMP notification. If the v1 or v2c security models are used, identify the SNMP community used when generating the notification.

NOTE: The access privileges for the group associated with this security name must allow this notification to be sent.

If you are using the v1 or v2 security models, the security name at the [edit snmp v3 vacm security-to-group] hierarchy level must match the security name at the [edit snmp v3 snmp-community *community-index*] hierarchy level.

Required Privilege Level

snmp—To view this statement in the configuration.

snmp-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

security-option (IDS Screen Next Gen Services)

IN THIS SECTION

- Syntax | 16504
- Hierarchy Level | 16504
- Description | 16505
- Required Privilege Level | 16505
- Release Information | 16505

Syntax

```
security-option;
```

Hierarchy Level

```
[edit services screen ids-option screen-name ip]
```

Description

Identify and drop IPv4 packets that have the IP option of 2 (Security).

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 19.3R2.

security-package

IN THIS SECTION

- Syntax | 16505
- Hierarchy Level | 16506
- Description | 16506
- Options | 16507
- Required Privilege Level | 16507
- Release Information | 16507

Syntax

```
security-package {
    automatic (Security) {
        download-timeout minutes;
```

```
        enable;
        interval hours;
        start-time start-time;
    }
    install {
        ignore-version-check;
        ignore-appid-failure;
    }
    proxy-profile proxy-profile;
    source-address address;
    url url-name;
}
```

Hierarchy Level

```
[edit security idp]
```

Description

Configure the device to automatically download the updated signature database from the specified URL.

When you configure signature installation to enable the `ignore-appid-failure` option, IDP signature download/installation does not fail even if application identification download/installation fails during IDP signature download/installation. This option is not enabled by default. You have to enable this option.

IDP signature package on an external server can be downloaded and installed on the SRX Series Firewall. Configure the `proxy profile` option of security package download to connect to the external server through a specified proxy server.

IDP uses proxy profile configured at the system level. The proxy profile being used in the security package must be configured at the `[edit services proxy]` hierarchy.

You can configure multiple proxy profiles under `[edit services proxy]` hierarchy. IDP can utilize only one proxy profile. Multiple proxy profiles are not supported for use under IDP simultaneously. When a proxy profile is configured under `[security idp security-package]` hierarchy, then the idpd process connects to the proxy host instead of the signature pack download server. The proxy host then communicates with the download server and provides the response back to the idpd process. The idpd process is notified every time there is a change made at the `[edit services proxy]` hierarchy.

Options

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.2.

Option `ignore-appid-failure` is introduced in Junos OS Release 18.3R1.

Option `proxy-profile` is introduced in Junos OS Release 18.3R1.

Description

Create a security profile and specify the kinds and amounts of resources to allocate to a logical system to which the security profile is bound.

As a primary administrator, you can create a security profile and bind it to more than one logical system if you want to allocate the same kinds and amounts of resources to them. For details on how many security profiles you can create, see *Understanding Logical Systems Security Profiles (Primary Administrators Only)*. When you reach the limit, you must delete a security profile and commit the configuration before you can create and commit the configuration for another security profile.

Only the primary administrator can create security profiles.

Options

profile-name	Name of the security profile.
resources	Name of the resources.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.2.

The `dslite-softwire-initiator` option introduced in Junos OS Release 12.1.

The `security-profile` option added under the `tenants` hierarchy in Junos OS Release 18.3R1.

The icap redirect profile option is introduced in Junos OS Release 18.3R1.

`secure-wire` option introduced in Junos OS Release 19.3R1.

Syntax

```
security-service (fail-open);
```

Hierarchy Level

```
[edit security forwarding-options]
```

Description

The system resource management guarantees the resources are used according to priorities. the fail-open/fail-close impacts the new session creation only when the system resource is busy.

- If system resource is not busy, fail-open/fail-close won't take effect. No impact to traffic.
- If system resource is busy and the new session need not be created with Layer 7 services that require the system resource, then no impact to traffic.
- . If system resource is busy, and the new session needs be created with Layer 7 services that require the system resource:
  - Fail-close (default), drops the packet and won't create the session
  - Fail-open, creates a flow session without the Layer 7 services that require the resource, and forward the packet out.

Options

- `fail-open`—Ignores Layer 7 services with resource requirements, creates a flow session without Layer 7 services, and forward the packet out.

Required Privilege Level

security—To view this in the configuration.

security-control—To add this to the configuration.

```

Description

Static segment for segment routing. A static segment is identified by a unique name. This segment type is assigned a segment identifier (SID) which falls under a default range of 100000 through 1048575. The segment has label operation such as pop-and-forward for adjacency segment and swap-and-forward for prefix or node segment. For both types of label operation, the segment is assigned a next hop that specifies the remote IP address if the outgoing interface is a multi-access interface, or the name of the outgoing interface if the interface is a point-to-point interface. Static segment configuration is used to statically configure or provision the adjacency SIDs, node SIDs, and prefix SIDs on transit routers.

Options

pop	Pop the SID label
swap	Swap the SID label to this label
description	Text description of label-switched path
next-hop	IPv4 address or interface of next-hop router
sid-label	Segment identifier (SID) label

The remaining statements are explained separately. See CLI Explorer.

    inherit-label-nexthops;
    srv6;
}
```

Hierarchy Level

```
[edit logical-systems name protocols source-packet-routing],
[edit protocols source-packet-routing]
```

Description

Specify an name to identify the segment routing list (used in traffic engineering policy) and the explicit path for source routing label switched path (LSPs) to traverse through traffic engineering segments. The segment list is essentially a stack of segment identifiers.

Starting in Junos OS release 19.1R1 for MX and PTX Series routers, you can enable a translation service to translate next-hop IP addresses into the corresponding segment identifier (SID) labels. The translation service keeps track of the node reached at each hop.

When configured, the `segment-list` of a segment routing traffic engineering (SR-TE) LSP accepts IP addresses for all the hops along the path. These IP addresses can be either the loopback address of a node, or the IP address of a link, as identified by the `node-type`. When `auto-translation` is enabled, next hop IP addresses are automatically translated to corresponding SIDs using the translation service. A retry rate can be set for the retry timer at the `source-packet-routing` hierarchy level.

> **NOTE**: The segment list enables BGP and static segment routing LSP to steer traffic based on segment routing policies. When a segment list is used by the protocol BGP, the BGP protocol validates these segment identifiers and selects valid segments for traffic engineering.

Options

name Specify a name to identify a SR-TE segment-list.

> **NOTE**: The combined length of tunnel-name and LSP name must not exceed 53 characters for per-path telemetry to work.

<hop-name> Indicates the next hop in the segment routing traffic engineering policy (SR-TE).

- **ip-address**—Specify the IP address of the hop. For a segment-list to be used by a non-colored segment routing LSP, the first hop must specify an IP address.
- **label**—Specify the SID label of the hop in a segment routing traffic engineering segment list. In static segment routing LSPs, the source routing path uses the segment list only if the second to Nth hop specifies segment identifiers (SID) labels.

  > **NOTE**: The range is from 0 to 1,048,576 and is applies to BGP and static segment routing LSPs.

- **label-type**—Use with the option below to indicate that the specified address is the IP address of the node, for example, its loopback address, as opposed to that of a link.
  - **node**—Hops that have been specified as `node` are translated to a prefix SID, which can be either a node SID or an anycast SID depending on the type of hop IP address. IP addresses not identified as `node` are consider to be a link.

    NOTE: If the first hop is a `node`, for LSP resolution to work correctly, `inherit-label-nexthops` must be enabled at either `source-packet-routing` hierarchy level, or at the relevant `segment-list` hierarchy level.

- **loose | strict**—IP hops specified using router IDs in the sequence can be strict or loose hops. A strict hop must be directly connected to the previous node in the sequence. A loose hop is not necessarily directly connected to the previous node.

  NOTE: You can specify only router IDs as loose or strict hop constraints. Labels and other IP addresses are not supported as loose or strict hop constraints in Junos OS Release 19.2R1-S1.

- **srv6-sid**—Indicates the SID for SRv6 segment-list in the form of IPv6 address.

  NOTE: An SRv6 segment-list can only have SRv6 SID which is a node SID (either the end-sid or end-x sid of the transit and end-sid of the egress nodes). Therefore, you need to correctly configure the last SRv6 SID in the segment-list as the end-sid of the egress PE.

auto-translate

This option must be enabled before a given segment list can use IP addresses instead of SIDs for any hop other than the first hop. In addition, all hops in the segment list must have IP addresses. If any hops on the list have both an IP address and a label configured, the label will be retained. Link addresses are only translated into labels if the preceding node advertises an adjacency SID for the address (otherwise translation fails).

NOTE: In Junos OS Release 19.1R1, for auto-translate to work for OSPF, RSVP for segment routing must be enabled on all participating interfaces.

- **protected**—(Optional) Enable this option to ensure the adjacency SID is eligible to have a backup path, and that a B-flag is set in adjacency SID advertisements. Note that unless `mandatory` is also selected, the choice succeeds regardless.
  - **mandatory**—(Optional) Enable this option to have translation fail if any *unprotected* links are found in the hop-list.
- **unprotected**—(Optional) Enable this option to ensure that no backup path is calculated for a specific adjacency SID, and that a B-flag is not set in adjacency SID advertisements. Note that unless `mandatory` is also selected, the choice succeeds regardless.
- **mandatory**—(Optional) Enable this option to have translation fail if any *protected* links are found the hop-list.

compute (Optional) Enable use of explicit paths specified in segment list for path computation.

inherit-label-nexthops Inherit label next hops for first hop in this segment list that have both IP address and label configured in the first hop.

You can configure the `inherit-label-nexthops` statement globally or individually for each segment list.

The `inherit-label-nexthops` statement takes effect only when the segment list first hop has both IP address and SID label present.

If the `inherit-label-nexthops` is not configured at the `[edit protocols source-packet-routing segment-list]` hierarchy, and the first hop in the segment list has both IP address and label specified, the default behavior is to use the IP address.

srv6 Specify SRv6 TE segment list.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

routing—To view this statement in the configuration.

[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name (primary |
secondary) path-name],
[edit protocols mpls label-switched-path lsp-name (primary | secondary) path-name]
```

Description

Specify the conditions under which the path is selected to carry traffic. The `manual` and `unconditional` options are mutually exclusive.

Options

`manual`—The path is selected for carrying traffic if it is up and stable for at least the revert timer window (potentially before the revert timer has elapsed). Traffic is sent to other working paths if the current path is down or degraded (receiving errors).

`unconditional`—The path is always selected for carrying traffic, even if it is currently down or degraded (receiving errors).

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

family-modifier add-path]
```

Description

Enable advertisement of multiple paths to a destination, instead of advertising only the active path.

NOTE: On PTX1000 devices, the `add-path` configuration statement is not supported under routing instances.

Options

include-backup-path

Configure the number of backup paths that BGP must advertise. Do not configure this option if you have configured `all-paths` at the `[edit protocols bgp group name family name add-path send]` hierarchy level.

- **Range:** 1 through 2

multipath

Restrict BGP `add-path` to advertise contributor multiple paths only. Advertising all available multiple paths might result in a large overhead of processing on device memory. Selective advertising of multiple paths facilitates Internet service providers and data centers that use route reflectors to build in-path diversity in IBGP. You can limit and configure up to six prefixes that the BGP `multipath` algorithm selects. You cannot configure both `multipath` and `path-selection-mode` at the same time.

For example, if a routing device has four paths to a destination in its routing table and is configured to advertise up to two paths, only contributor paths for load balancing are chosen. The best contributor path is the active path and BGP advertises this path by default. The second best contributor path is selected and this process is repeated until the specified number of paths is reached; in this case, two additional paths to the same destination are selected for load balancing.

path-count ***number***

Specify the number of paths to a destination to advertise.

Suppose a routing device has in its routing table four paths to a destination and is configured to advertise up to three paths (`add-path send path-count 3`). The three paths are chosen based on path selection criteria. That is, the three best paths are chosen in path-selection order. The best path is the active path. This path is removed from consideration and a new best path is chosen. This process is repeated until the specified number of paths is reached.

- **Range:** 2 through 64
- **Default:** 1

path-selection-mode

Specify whether BGP can advertise all the available paths or only the equal-cost paths. BGP can advertise up to 64 add-path routes and a second best ECMP path as a backup in addition to the multiple ECMP paths. You cannot configure both `multipath` and `path-selection-mode` at the same time.

- Values:
  - all-paths—Specify the total number of add-path routes to advertise. BGP advertises all the paths that are allowed by the configured prefix policy and the maximum paths configured using the `path-count` option.
  - equal-cost-paths—Specify the equal-cost paths to advertise. You can configure either this option or the `multipath` option; they are mutually exclusive.

prefix-policy ***policy-names***

Specify the name of a policy (or a set of policies) configured at the `[edit policy-options]` hierarchy level to filter the paths to a destination to advertise.

Prefix policies enable you to filter routes on a router that is configured to advertise multiple paths to a destination. Prefix policies can only match prefixes. They cannot match route attributes, and they cannot change the attributes of routes.

The `add-path prefix-policy` allows up to 64 BGP add-paths to be advertised for a subset of prefixes that match the add-path prefix-policy. To enable this feature for a prefix, the `add-path prefix-policy` term matching the prefix should have a new *then* action to set `add-path send-count` *<2...64>*. This new action is not applicable if the policy-statement containing it is used in any place other than `add-path prefix-policy`.

- **Range:** 2 through 64 (for BGP)

> **NOTE**: This range is applicable only under `prefix-policy add-path`.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.3.

Support for range from 2 through 20 (for BGP) introduced in Junos OS Release 14.1.

`multipath` option introduced in Junos OS Release 16.1R2.

Support for 64 BGP add-paths introduced in Junos OS Release 18.4R1 for the MX Series.

`include-backup-path` and `path-selection-mode` options introduced in Junos OS Release 18.4R1 for the MX Series and PTX Series.

send-dyn-subscription-indicator (PCRF Partition)

IN THIS SECTION

- Syntax | 16540
- Hierarchy Level | 16540
- Description | 16540
- Required Privilege Level | 16541
- Release Information | 16541

Syntax

```
send-dyn-subscription-indicator;
```

Hierarchy Level

```
[edit access pcrf partition partition-name],
```

Description

Include the Juniper-Network-Family-Indicator AVP into its message requests. To enable the Policy Control and Charging Rules Function (PCRF) to dynamically pass subscription-ID parameters, and support a variety of authentication, authorization, and provisioning configuration, the Juniper attribute-value pairs (AVPs) in Table 138 on page 16541 have been allocated from the Juniper Vendor-ID space (2636) vendor-specific attribute (VSA).

NOTE: If no dynamic-subscription ID is received, then neither Online Charging System (OCS) or Offline Charging System (OFCS) communications is initiated.

Table 138: Allocated Juniper AVPs

AVP Name	Vendor-ID	AVP Type	Diameter Type	Diameter Flag
Juniper-Dyn-Subscription-Indicator	2636	10001	Enum	V
Juniper-Dyn-Subscription-Id	2636	10002	Grouped	VM
Juniper-Dyn-Subscription-Id-Type	2636	10003	Integer32	VM
Juniper-Dyn-Subscription-Id-Data	2636	10004	UTF8String	VM

The client system (router) sends the Juniper-Dyn-Subscription-Id-Indicator AVP to indicate support of the dynamic assignment of the subscription ID. The Juniper-Dyn-Subscription-Id-Indicator attribute has two values:

- DYN_SUBSCRIPTION_NOT_SUPPORTED (0)
- DYN_SUBSCRIPTION_SUPPORTED (1)

The server then sends the Juniper-Dyn-Subscription-Id AVP to the client that indicated support. This is a grouped AVP that contains the values to be sent as Subscription-Id-Type and Subscription-Id-Data.

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 16.2.

- Release Information | 16543

Syntax

```
send-network-family-indicator;
```

Hierarchy Level

```
[edit access pcrf partition partition-name]
```

Description

Include the Juniper-Network-Family-Indicator AVP into its message requests. In many cases, wireline subscribers support only one IP family, which is required information for both AAA service and Policy Control and Charging Rules Function (PCRF). To indicate this information, the Juniper-Network-Family-Indicator AVP has been allocated from the Juniper Vendor-ID space (2636) VSA in Table 139 on page 16543.

Table 139: Network Family Indicator AVP

AVP Name	Vendor-ID	AVP Type	Diameter Type	Diameter Flag
Juniper-Network-Family-Indicator	2636	10010	Enum	V

The client system (router) sends the Juniper-Network-Family-Indicator AVP to indicate which network families are associated with the service request and supported by the subscriber. When you configure the Juniper-Network-Family-Indicator AVP to indicate the associated network family, the system sends the information to the PCRF. The Juniper-Network-Family-Indicator attribute has four values:

- UNSPECIFIED (0)
- IPV4_FAMILY (1)
- IPV6_FAMILY (2)
- IPV4_IPV6_FAMILY (3)

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 16.2.

send-origin-state-id (Diameter Applications)

IN THIS SECTION

- Syntax | 16545
- Hierarchy Level | 16545
- Description | 16545
- Required Privilege Level | 16546
- Release Information | 16546

Syntax

```
send-origin-state-id;
```

Hierarchy Level

```
[edit access pcrf partition partition-name],
[edit access ocs partition partition-name],
[edit diameter peer peer-name]
```

Description

Include the Origin-State AVP for the Diameter peer, OCS partition, or PCRF partition. The AVP is conveyed in Diameter-level or partition-level messages, respectively. The value of the AVP increases every time it changes, such as when the system reboots. Sending the Origin-State AVP in messages enables Diameter entities that receive the message to infer from a changed AVP value that sessions associated with a lower value are no longer active.

If you include the `send-origin-state-id` statement for the OCS or PCRF partition, a new value is sent for the partition only when a cold boot occurs. The system daemon detects the cold boot and changes the Origin-State-Id when required.

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 16.2.

Description

Send a release message to the DHCP (or DHCPv6) server whenever DHCP relay or relay proxy deletes a client. Use the statement at the `[edit ... dhcpv6]` hierarchy levels to configure DHCPv6 support.

M120 and M320 routers do not support DHCPv6.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.2.

Support at the `[edit ... dhcpv6]` hierarchy levels introduced in Junos OS Release 11.4.

mvpn],
[edit routing-instances routing-instance-name protocols mvpn]
```

Description

In a BGP multicast VPN (MVPN) with either RSVP-TE point-to-multipoint or MLDP point-to-multipoint provider tunnels, configure a downstream provider edge (PE) router to forward multicast traffic only from a selected upstream sender PE router.

Starting in Junos OS Release 21.1R1, you can configure MLDP point-to-multipoint provider tunnel on MX Series router.

BGP MVPNs use an alternative to data-driven-event solutions and bidirectional mode DF election because, for one thing, the core network is not exactly a LAN. Because, in an MVPN scenario, it is possible to determine which PE router has sent the traffic, Junos OS uses this information to only forward the traffic if it is sent from the correct PE router. With sender-based RPF, the RPF check is enhanced to check whether data arrived on the correct incoming virtual tunnel (vt-) interface and that the data was sent from the correct upstream PE router.

More specifically, the data must arrive with the correct MPLS label in the outer header used to encapsulate data through the core. The label identifies the tunnel and, if the tunnel is point-to-multipoint, the upstream PE router.

Sender-based RPF is not a replacement for single-forwarder election, but is a complementary feature. Configuring a higher primary loopback address (or router ID) on one PE device (PE1) than on another (PE2) ensures that PE1 is the single-forwarder election winner. The `unicast-umh-election` statement causes the unicast route preference to determine the single-forwarder election. If single-forwarder election is not used or if it is not sufficient to prevent duplicates in the core, sender-based RPF is recommended.

For RSVP point-to-multipoint provider tunnels, the transport label identifies the sending PE router because it is a requirement that penultimate hop popping (PHP) is disabled when using point-to-multipoint provider tunnels with MVPNs. PHP is disabled by default when you configure the MVPN protocol in a routing instance. The label identifies the tunnel, and (because the RSVP-TE tunnel is point-to-multipoint) the sending PE router.

The sender-based RPF mechanism is described in RFC 6513, *Multicast in MPLS/BGP IP VPNs* in section 9.1.1.

Sender-based RPF prevents duplicates from being sent to the customer even if there is duplication in the provider network. Duplication could exist in the provider because of a hot-root standby configuration or if the single-forwarder election is not sufficient to prevent duplicates. Single-forwarder election is used to prevent duplicates to the core network, while sender-based RPF prevents duplicates to the customer even if there are duplicates in the core. There are cases in which single-forwarder election cannot prevent duplicate traffic from arriving at the egress PE router. One example of this (outlined in section 9.3.1 of RFC 6513) is when PIM sparse mode is configured in the customer network and the MVPN is in RPT-SPT mode with an I-PMSI.

Description

Configures Junos OS to send the sender ID TLV along with the packets. The sender ID TLV is an optional TLV that is sent in continuity check messages (CCMs), loopback messages, and Link Trace Messages (LTMs), as specified in the IEEE 802.1ag standard. TLVs (type, length, and value) are described in the IEEE 802.1ag standard for Connectivity Fault Management (CFM) as a method of encoding variable-length and optional information in a protocol data unit (PDU).

```

```
[edit protocols (ospf | ospf3) source-packet-routing]
```

Description

Enable the collection of aggregate segment routing statistics for the Source Packet Routing in Networking (SPRING) traffic only, excluding RSVP and LDP-signaled traffic. Family MPLS statistics per interface are accounted for separately. The SR statistics also include SPRING traffic statistics per link aggregation group (LAG) member and per segment identifier (SID). The statistics are collected using the Juniper telemetry interface in an OpenConfig compliant format for Layer 3 interfaces.

> **NOTE**: This statement is also available for LDP and MPLS statistics. For more information see "sensor-based-stats (Junos Telemetry Interface)" on page 16558.
>
> For additional information about configuring these statistics sensors to stream data through gRPC, see *Guidelines for gRPC and gNMI Sensors (Junos Telemetry Interface)*.

Enables the collection of on box telemetry spring sensor-based traffic statistics using the `subscribe` statement. As a result, the configuration triggers and records the on box telemetry for spring sensor-based statistics. The configuration creates a connection with network-agent and subscribes to the configured sensor path. The sensor path is installed on the Packet Forwarding Engine.

Options

per-interface-per-member-link

Configure sensor-based statistics per nexthop. Sensor-based statistics is the traffic statistics in a segment routing (SR) network that can be recorded in an OpenConfig compliant format for Layer 3 interfaces. The statistics is recorded for the Source Packet Routing in Networking (SPRING) traffic only, excluding RSVP and LDP-signaled traffic, and the family MPLS statistics per interface is accounted for separately. The SR statistics also includes SPRING traffic statistics per link aggregation group (LAG) member, and per segment identifier (SID).

egress Enable sensor based statistics on the egress interface.

ingress Enable sensor based statistics on the ingress interface.

> **NOTE**: On PTX Series Routers, the sensor-based statistics for SPRING traffic is recorded at the ingress interface only.

per-sid

Configure sensor based statistics per Source Packet Routing in Networking (SPRING) route. Sensor-based statistics is the traffic statistics in a segment routing (SR) network that can be recorded in an OpenConfig compliant format for Layer 3 interfaces. The statistics is recorded for SPRING traffic only, excluding RSVP and LDP-signaled traffic, and the family MPLS statistics per interface is accounted for separately. The SR statistics also includes SPRING traffic statistics per link aggregation group (LAG) member, and per segment identifier (SID).

egress Enable sensor based statistics for IP-MPLS egress accounting. This is supported only for segment routing label egress routes at the ingress provider edge (PE) device.

ingress Enable sensor based statistics for per-sid ingress accounting.

subscribe

Enables the collection of on box telemetry spring sensor- based traffic statistics with the interval range for interval configurationbetween 30 to 86400 seconds.

interval "interval" configuration indicates the time interval for sampling the telemetry updates. The configured range for interval can vary from 30 to 86400 seconds.

Required Privilege Level

routing—To view this statement in the configuration.

Release Information

Statement introduced in Junos OS Release 17.4R1.

Support at the `[edit protocols (ospf | ospf3) source-packet-routing]` hierarchy level introduced in Junos OS Release 23.1R1 and Junos OS Evolved Release 23.1R1.

Description

Enable the collection of certain statistics for the Junos telemetry interface. You must configure this statement when you configure a sensor to monitor and stream data for the following statistics:

- LDP—Enable the collection of LDP traffic statistics. Use the `resource` option at the `[edit services analytics sensor sensor-name]` hierarchy level to configure one of the LDP statistics sensors to stream data through UDP.
- MPLS—Enable the collection of LSP statistics. To enable a sensor to stream data for LSP statistics through UDP, include the `resource /junos/services/label-switched-path/usage/` statement at the `[edit services analytics sensor sensor-name]` hierarchy level.

> **NOTE**: This statement is also available for IS-IS statistics on MX Series, PTX3000, and PTX5000 routers. For more information, see *Understanding Source Packet Routing in Networking (SPRING)* and "sensor-based-stats (Protocols IS-IS)" on page 16555.

For additional information about configuring these statistics sensors to stream data through gRPC, see *Guidelines for gRPC and gNMI Sensors (Junos Telemetry Interface)*.

Required Privilege Level

routing—To view this statement in the configuration.

Description

Configure various IDP parameters to match the properties of transiting network traffic.

Options

- `ssl-profile-name` *`profile-name`* —SSL initiation profile name to be used for encrypted packet log transmission.

  Starting in Junos OS Release 22.1R1, you can enable a secure SSL connection and send encrypted IDP packet capture log to the packet capture receiver. To establish the SSL connection you must specify the SSL initiation profile you want to use in the IDP packet log configuration.

  The SSL profile name must be configured in the SSL initiation profile configuration. Configuration and installation of SSL certificates and SSL handshake related configurations that are required to establish secure connection are performed as part of SSL initiation profile configuration. SSL versions are chosen based on the SSL initiation configuration. SSL profile needs to be configured in each logical system separately .

  If SSL profile name is not configured in SSL initiation profile configuration, then the following message is displayed **Referenced SSL initiation profile is not defined**.

The remaining statements are explained separately. See CLI Explorer.

- Syntax | **16564**
- Hierarchy Level | **16565**
- Description | **16565**
- Options | **16565**
- Required Privilege Level | **16592**
- Release Information | **16592**

Syntax

```
sensor sensor-name {
    export-name export-profile-name;
    polling-interval seconds;
    resource resource-string;
    <resource-filter regular expression>;
    server-name [ streaming-server-names ];
}
```

Hierarchy Level

```
[edit services analytics]
```

Description

Configure a Junos telemetry interface sensor, which defines the parameters of a system resource to monitor and stream data. You can use regular expressions to filter the data collected. Examples include filters for logical and physical interfaces and LSP messages. To apply different filters to the same system resource, you configure multiple sensors. For example, you can configure multiple logical interface sensors and apply a different interface filter to each one.

Options

Each sensor configuration requires you to specify the following: sensor name, an export profile name, a resource identifier string that enables monitoring and streaming of data for the specified system resource, and a server name to collect data. A regular expression to filter data for the specified resource is optional.

sensor-name

Specify a name that defines the sensor configuration. For example, for a sensor configuration that monitors all LSP events, you might choose the name `lsp-mon-global`. For a sensor configuration that monitors events only for an LSP named A2B, you might choose the name `lsp-mon-A2B`.

export-name ***export-profile-name***

Specify the name of an export profile that you configured at the [`edit services analytics export-profile` *name*] hierarchy level to associate with the sensor. This export profile defines the parameters for exporting telemetry data, such as a format for exported data and the rate at which data is generated for export.

> **NOTE**: You can apply only one export profile to each sensor configuration. The only supported transport protocol when you configure a sensor through the CLI is UDP.

polling-interval ***seconds***

Specify the interval at which the Junos Telemetry Interface sensor generates data to export to the collector.

As the configured interval expires, the most recent sample collected by the sensor is gathered and forwarded to the server configured to collect data.

> **NOTE**: For Packet Forwarding Engine sensors, the minimum reporting rate is 2 seconds.

- **Range:** 1 through 3600 (1 hour)

resource *resource-string*

Enable the system resource to monitor and stream data. Each string corresponds to a specific system resource. The format is a file path and must be entered exactly. You can associate only one *resource-string* with a *sensor-name*. Configure a separate sensor for each system resource you want to monitor. The resource string to enable LSP monitoring can be modified to specify a specific LSP.

> **NOTE**: You can configure more than one sensor to monitor the same system resource. Configuring different sensors for the same system resource allows you configure different parameters for monitoring that resource.

Table 140 on page 16566 lists each supported *resource-identifier-string*, a description of the system resource monitored, and additional configuration information.

You can also use the Telemetry Explorer tool to search for and view information about *resource-identifier-string*.

Table 140: resource statement Options

resource string	Description	Release Information
/interfaces/interface/ethernet/state/counters/jnx-pfc-statistics	Transport statistics providing pause frame receive and transmit counter support.	Junos OS Evolved Release 21.4R1 and later on PTX10001-36MR, PTX10004, PTX10008, and PTX10016 routers.

Table 140: resource statement Options *(Continued)*

resource string	Description	Release Information
/junos/events	System events sensor. Starting with Junos OS Release 18.1R1, this sensor corresponds to system log messages (syslog). The sensor must be used with an `export-profile` that has a `reporting-rate` of 0, To subscribe for specific events, you can subscribe for /junos/events/event[id='EVENT_NAME'] where event EVENT_NAME is the event id that you are interested in. Alternatively, you can subscribe to any XPATH Many event names can be found in the messages log file.	Junos OS 18.1R1 and later on all JTI platforms.
/junos/services/ip-tunnel/usage/	Packet Forwarding Engine packet statistics sensor. The statistics are used to report various network element performance metrics in a scalable and efficient way, providing visibility into Packet Forwarding Engine errors and drops. A timestamp indicating when the counters were last reset is included with all the exported data to allow collectors to determine if and when a reset event happened; for example, if the Packet Forwarding Engine hardware restarted. Exported statistics are similar to the output of the operational mode command `show nhdb hw dynamic-ip-tunnels`.	Junos OS 17.4R1 and later on MX Series devices.

Table 140: resource statement Options *(Continued)*

resource string	Description	Release Information
/junos/services/label-switched-path/usage/	Packet Forwarding Engine sensor for LSP statistics. Starting with Junos OS Release 17.4R1 on MX Series and PTX Series routers only, statistics for bypass LSPs are also exported. Previously, only statistics for ingress LSPs were exported. For bypass LSPs, the following are exported: • Bypass LSP originating at the ingress router of the protected LSP • Bypass LSP originating at the transit router of the protected LSP • Bypass LSP protecting the transit LSP as well as the locally originated LSP When the bypass LSP is active, traffic is exported both on the bypass LSP and the ingress (protected) LSP. On MX Series routers only, bidirectional LSPs for ultimate-hop popping (UHP) are also supported. **NOTE**: You can modify `/junos/services/label-switched-path/usage/` to specify a specific LSP. Add `__instance__/`*`lsp-name`* to the end of the resource string identifier. For example, to monitor and stream data for LSP statistics for an LSP named mirror-to-murano-1, enter the following: `/junos/services/label-switched-path/usage/ __instance__/mirror-to-murano-1`. If you do not specify a specific LSP name, the system resource monitors and streams data for all LSPs. When you enable a sensor for LSP statistics, you must also configure the `sensor-based-stats` statement at the `[edit protocols mpls]` hierarchy level. MX Series routers must also operate in enhanced mode. If not enabled by default, configure either the `enhanced-ip` statement or the `enhanced-ethernet` statement at the `[edit chassis network-services]` hierarchy level.	Junos OS Release 15.1F6 and later. Junos OS Release 17.2R1 and later on QFX10000 switches and PTX1000 routers. Junos OS Release 17.3 and later on EX9200 and QFX5110 switches. Junos OS Release 18.2R1 and later on QFX5100, QFX5110, and QFX5200 switches Junos OS Release 18.3R1 and later on QFX5120-48Y and EX4650 switches Junos OS Release 18.4R1 and later on EX4600 switches Junos OS Release 19.1R1 and later on QFX10002 switches and PTX10002 routers

Table 140: resource statement Options *(Continued)*

resource string	Description	Release Information
/junos/services/ldp/label-switched-path/ingress/usage/	Packet Forwarding Engine sensor for LDP LSP ingress statistics. When you enable a sensor for LDP statistics, you must also configure the `sensor-based-stats` statement at the `[edit protocols ldp traffic-statistics]` hierarchy level. On PTX Series routers, this feature is not supported for the following variants: • PTX3000 and PTX5000 with the RE-DUO-C2600-16G Routing Engine • PTX10008 with the PTX10K-LC1201-36CD line card	Junos OS Release 20.2R1 for MX series and PTX series routers. Junos OS Release 20.3R1 on MPC10E-10C-MRATE, MPC10E-15C-MRATE, and MX2K-MPC11E line cards.
/junos/services/ldp/label-switched-path/transit/usage/	Packet Forwarding Engine sensor for LDP LSP transit statistics. On PTX Series routers, this feature is not supported for the following variants: • PTX3000 and PTX5000 with the RE-DUO-C2600-16G Routing Engine • PTX10008 with the PTX10K-LC1201-36CD line card	Junos OS Release 20.2R1 for MX series and PTX series routers. Junos OS Release 20.3R1 on MPC10E-10C-MRATE, MPC10E-15C-MRATE, and MX2K-MPC11E line cards.

Table 140: resource statement Options *(Continued)*

resource string	Description	Release Information
/junos/services/ldp/p2mp/interface/receive/usage/	Packet Forwarding Engine sensor for LDP P2MP receive statistics. On PTX Series routers, this feature is not supported for the following variants: • PTX3000 and PTX5000 with the RE-DUO-C2600-16G Routing Engine • PTX10008 with the PTX10K-LC1201-36CD line card	Junos OS Release 20.2R1 for MX series and PTX series routers. Junos OS Release 20.3R1 on MPC10E-10C-MRATE, MPC10E-15C-MRATE, and MX2K-MPC11E line cards.
/junos/services/ldp/p2mp/interface/transmit/usage/	Packet Forwarding Engine sensor for LDP P2MP transmit statistics. On PTX Series routers, this feature is not supported for the following variants: • PTX3000 and PTX5000 with the RE-DUO-C2600-16G Routing Engine • PTX10008 with the PTX10K-LC1201-36CD line card	Junos OS Release 20.2R1 for MX series and PTX series routers. Junos OS Release 20.3R1 on MPC10E-10C-MRATE, MPC10E-15C-MRATE, and MX2K-MPC11E line cards.
/junos/services/ldp/p2mp/label-switched-path/usage/	Packet Forwarding Engine sensor for LDP P2MP LSP statistics. On PTX Series routers, this feature is not supported for the following variants: • PTX3000 and PTX5000 with the RE-DUO-C2600-16G Routing Engine • PTX10008 with the PTX10K-LC1201-36CD line card	Junos OS Release 20.2R1 for MX series and PTX series routers. Junos OS Release 20.3R1 on MPC10E-10C-MRATE, MPC10E-15C-MRATE, and MX2K-MPC11E line cards.

Table 140: resource statement Options *(Continued)*

resource string	Description	Release Information
/junos/services/segment-routing/sid/usage/	Source Packet Routing in Networking (SPRING) sensorSfor transit statistics. SPRING is also known as segment routing. Before statistics can be exported, you must first enable them by including the `sensor-based-stats` statement at the `[edit protocols isis source-packet-routing]` hierarchy level. For more information, see *Enabling Export of Transit SPRING Statistics*.	Junos OS Release 19.1R1 and later on PTX3000 routers and PTX5000 with FPC2
/junos/services/spu/delegated-rpm/	Delegated Realtime Performance Monitoring (RPM) service sensor. Delegated RPM is a mode where RPM probe generation and measurement calculation are done by MS-MIC and MS-MPC cards. This hardware assistance allows a very high scale of concurrent RPM probes. You can use the resulting data from this sensor to improve network design and optimize traffic engineering. Data can also be used to detect problems in individual devices as well as in the overall network and the traffic carried by it. JTI sensor support for other RPM modes was added in Junos OS Release 18.3R1. This sensor has the following limitations: • Configuring multiple export profiles for the same resource for delegated RPM may not provide expected results. • Multiple sensors for single resource-path (such as delegated RPM) is not supported. • Due to an egress packet-size limitation, history outputs are limited to 5 per RPM test. • The sensor exports one RPM test record per export packet.	Junos OS Release 19.1R1 and later on MX Series routers operating with MS-MIC and MS-MPC

Table 140: resource statement Options *(Continued)*

resource string	Description	Release Information
/junos/services/spu/ipsec-vpn	UDP-based PIC sensors. Starting with Junos OS Release 18.1R1, this sensor provides visibility for IPSec services on different service complexes and nodes. Exported data is defined using an IP address and a UDP port. When an export interval expires, the most recent statistics collected by the sensors are gathered, placed in the payload of a UDP packet, and forwarded to a collector. A timestamp indicating when counters are read is included with the exported data to allow collectors to collate data. The timestamp also can determine if and when an event happened, such as a PIC hardware restart or if counters were cleared by means of the CLI.	Junos OS 18.1R1 on MX Series with MS-MICs and MS-MPCs
/junos/services/spu/servicesets	Sensor to export service set statistics. These sensors provide visibility for services on different service complexes and nodes (for example, IPSec services). Exported data is defined using an IP address and a UDP port. When an export interval expires, the most recent statistics collected by the sensors are gathered, placed in the payload of a UDP packet, and forwarded to a collector. A timestamp indicating when counters are read is included with the exported data to allow collectors to collate data. The timestamp also can determine if and when an event happened, such as a PIC hardware restart or if counters were cleared by means of the CLI.	Junos OS 18.2R1 on MX Series with MS-MICs and MS-MPCs

Table 140: resource statement Options *(Continued)*

resource string	Description	Release Information
/junos/services/spu/sessions	Sensor to export session statistics. These sensors provide visibility for services on different service complexes and nodes (for example, IPSec services). Exported data is defined using an IP address and a UDP port. When an export interval expires, the most recent statistics collected by the sensors are gathered, placed in the payload of a UDP packet, and forwarded to a collector. A timestamp indicating when counters are read is included with the exported data to allow collectors to collate data. The timestamp also can determine if and when an event happened, such as a PIC hardware restart or if counters were cleared by means of the CLI.	Junos OS 18.2R1 on MX Series with MS-MICs and MS-MPCs
/junos/system/linecard/node-slicing/af-fab-stats/	Sensor to export abstracted fabric (AF) interface specific load-balancing and fabric queue statistics. This sensor is only supported for a node virtualization configuration on MX series routers with an AF Interface as the connecting link between guest network functions (GNFs). The sensor also reports aggregated statistics across all AF interfaces hosted on a source packet forwarding engine of local GNFs along with the fabric statistics for all traffic ingressing from and egressing to the fabric from that the packet forwarding engine.	Junos OS Release 18.4R1 and later on MX480, MX960, MX2008, MX2010, MX2020, and MX-ELM routers

Table 140: resource statement Options *(Continued)*

resource string	Description	Release Information
/junos/system/linecard/cos/interface/interface-set/output/queue/	Sensor for logical interface (IFL)-set. The sensor streams queue statistics using Juniper proprietary gRPC and gNMI or by means of UDP. Zero suppression (suppressing zero values in statistics from streamed data) is also supported.	Junos OS Release 22.3R1and later on MX204, MX240, MX304, MX480, MX960, MX2010, MX2020, MX10003, MX10004, MX10008, and MX10016 routers with Trio chipset EA, ZT, and YT-based fixed systems and modular systems linecards.

Table 140: resource statement Options *(Continued)*

resource string	Description	Release Information
/junos/system/linecard/cpu/memory/	Packet Forwarding Engine sensor for CPU memory.	Junos OS Release 16.1R3 and later. Junos OS Release 17.2R1 and later on QFX10000 switches and PTX1000 routers. Junos OS Release 17.3R1 and later on EX9200 and QFX5110 switches. Junos OS Release 18.2R1 and later on QFX5100, QFX5110, and QFX5200 witches Junos OS Release 18.3R1 and later on QFX5120-48Y and EX4650 switches Junos OS Release 18.4R1 and later on EX4600 switches Junos OS Release 19.1R1 and later on QFX10002 switches and PTX10002 Routers Junos OS Release 20.2R1 and later on EX2300, EX2300-MP, and EX3400 switches

Table 140: resource statement Options *(Continued)*

resource string	Description	Release Information
/junos/system/linecard/ddos/	Distributed denial of service (DDoS) sensor. This sensor supports the Openconfig data model junos/ui/openconfig/yang/ and junos-ddos.yang. You can stream information using Juniper proprietary gRPC or UDP (native) export. There are 45 packet types for DDoS. To maintain a reasonably sized data stream, data is exported for all protocols that have seen traffic using the zero-suppression model. On QFX5000 platforms, multiple protocols can share the same CPU queue. DDoS configurations are applied at the CPU queue level. Consequently, DDoS statistics fetched from the CPU queue will return the aggregate value of all protocols using that queue. For example, if BGP, LDP, and RSVP protocols are using a particular CPU queue, but the DDoS limit is violated only by the BGP protocol, the DDoS violation reported will include all three protocols: BGP, LDP, and RSVP. This information will be exported to the collector with the DDoS sensor.	Junos OS Release 22.1R1 and later on EX4650, QFX5110, QFX5120-48Y, QFX5200 and QFX5210 switches Junos OS Evolved Release 22.3R1 and later on PTX10001-36MR, PTX10003, PTX10004, PTX10008 and PTX10016 routers.
/junos/system/linecard/environment/	FPC environment sensor `/junos/system/linecard[name=FPC0]/environment/` is supported to stream voltage, temperature, and power information. You can stream the following endpoints: • `/power-record/max-fpc-power` `/power-record/fpc-power` • `voltage-record/voltage-sensor-name` • `voltage-record/voltage-value` • `temp-sensor-name` • `temp-record/temp-value`	Junos OS Release 22.4R1 and later on MX10004 routers.

Table 140: resource statement Options *(Continued)*

resource string	Description	Release Information
/junos/system/linecard/firewall/	Packet Forwarding Engine sensor for firewall filter counters and policer counters. Each line card reports counters separately. **NOTE**: Hierarchical policer statistics are collected for MX Series routers only. Traffic-class counter statistics are collected for PTX Series routers and QFX10000 switches only. Firewall counters are exported even if the interface to which the firewall filer is attached is down.	Junos OS Release 15.1F5 and later. Junos OS Release 17.2R1 and later on QFX10000 switches. Junos OS Release 17.3R1 and later on PTX1000 routers and EX9200 switches and QFX5110 switches. Junos OS Release 18.2R1 and later on QFX5100, QFX5110, and QFX5200 switches Junos OS Release 18.3R1 and later on QFX5120-48Y and EX4650 switches Junos OS Release 18.4R1 and later on EX4600 switches Junos OS Release 20.2R1 and later on EX2300, EX2300-MP, and EX3400 switches.

Table 140: resource statement Options *(Continued)*

resource string	Description	Release Information
/junos/system/linecard/interface/	Packet Forwarding Engine sensor for physical interface traffic. **NOTE**: For PTX Series routers, for a specific interface, queue statistics are exported for each line card. For MX series routers, interface queue statistics are exported only from the slot on which an interface is configured. For Aggregated Ethernet interfaces, statistics are exported for the member physical interfaces. You must aggregate the counters at the destination server, or collector. If a physical interface is administratively down or operationally down, interface counters are not exported. Issuing an operational `clear` command, such as `clear interfaces statistics all`, does not reset statistics exported by the line card.	Junos OS Release 15.1F3 and later on PTX Series routers only. Support introduced for MX Series routers in Junos OS Release 15.1F5. Junos OS Release 17.2R1 and later on QFX10000 switches and PTX1000 routers. Junos OS Release 17.3R1 and later on EX9200 switches, QFX5110 switches and MX150 routers. Junos OS Release 18.2R1 and later on QFX5100, QFX5110, and QFX5200 switches Junos OS Release 18.3R1 and later on QFX5120-48Y and EX4650 switches Junos OS Release 18.4R1 and later on EX4600 switches Junos OS Release 19.1R1 and later on QFX10002 Switches and PTX10002 routers

Table 140: resource statement Options *(Continued)*

resource string	Description	Release Information
		Junos OS Release 20.2R1 and later on EX2300, EX2300-MP, and EX3400 switches Junos OS Evolved Release 20.2R1 and later on PTX10008 routers. UDP streaming is not supported over the management interface.

Table 140: resource statement Options *(Continued)*

resource string	Description	Release Information
/junos/system/linecard/interface/logical/usage/	Packet Forwarding Engine sensor for logical interface statistics. **NOTE**: If a logical interface is operationally down, interface statistics continue to be exported. Issuing an operational `clear` command, such as `clear interfaces statistics all`, does not reset statistics exported by the line card. **NOTE**: Locally injected packets from the Routing Engine are not exported.	Junos OS Release 15.1F5 and later. Junos OS Release 17.2R1 and later on QFX10000 switches. Junos OS Release 17.3R1 and later on EX9200 and QFX5110 switches Junos OS Release 18.2R1 and later on QFX5100, QFX5110, and QFX5200 switches Junos OS Release 18.3R1 and later on QFX5120-48Y and EX4650 switches Junos OS Release 18.4R1 and later on EX4600 switches Junos OS Release 20.2R1 and later on EX3400 switches Junos OS Evolved Release 20.2R1 and later on PTX10008 routers. UDP streaming is not supported over the management interface.

Table 140: resource statement Options *(Continued)*

resource string	Description	Release Information
/junos/system/linecard/interface/queue/	Packet Forwarding Engine sensor for physical interface traffic. Exports all queue fields from /junos/system/linecard/interface/. To export traffic and queue data for physical interfaces, use /junos/system/linecard/interface/. To export traffic fields only, use /junos/system/linecard/interface/traffic/.	Junos OS Release 18.3R1 and later on PTX Series and ACX Series routers and EX Series, MX Series, and QFX Series switches.
/junos/system/linecard/interfaces/logical/usage/	Packet Forwarding Engine sensor for logical interface statistics.	Junos OS Evolved Release 21.4R1 and later on PTX10001-36MR, PTX10004, PTX10008, and PTX10016 routers.
/junos/system/linecard/interfaces/traffic/	Packet Forwarding Engine sensor for physical interface traffic. Exports traffic fields only	Junos OS Evolved Release 21.4R1 and later on PTX10001-36MR, PTX10004, PTX10008, and PTX10016 routers.
/junos/system/linecard/intf-exp/	Interface express sensor. This sensor leverages statistics out of the physical interface sensor, providing faster and more frequent operational status statistics. Only the physical interfaces' operational status from the Flexible PIC Concentrator (FPC) is collected and reported. Statistics from the Routing Engine interface are not reported.	Junos OS Release 18.1R1 and later on PTX1000, PTX3000, PTX5000, and PTX10000 routers. Junos OS Release 19.3R1 and later on MX960, MX2010, and MX2020 routers.

Table 140: resource statement Options *(Continued)*

resource string	Description	Release Information
/junos/system/linecard/npu/memory/	Packet Forwarding Engine sensor for network processing unit (NPU) memory.	Junos OS Release 16.1R3 and later. Junos OS Release 17.2R1 and later on QFX10000 switches. Junos OS Release 17.3R1 and later on EX9200 switches. Junos OS Release 19.1R1 and later on PTX10002 routers. Junos OS Evolved Release 20.2R1 and later on PTX10008 routers. UDP streaming is not supported over the management interface. Junos OS Release 21.4R1 and later on EX4650, QFX5110, QFX5120-48Y, QFX5200, and QFX5210 switches. Supported on QFX5130, QFX5700, QFX5220-32CD, QFX5220-128C, QFX5130-48C, QFX5130-48CM, QFX5130E-32CD, QFX5230-64CD, QFX5240-64QD,

Table 140: resource statement Options *(Continued)*

resource string	Description	Release Information
		and QFX5240-64QD switches starting with Junos OS Release 24.4R1 for exporting telemetry information using gRPC or gNMI services.
/junos/system/linecard/npu/utilization/	Packet Forwarding Engine sensor for NPU processor utilization.	Junos OS Release 16.1R3 and later. Junos OS Release 17.2R1 and later on QFX10000 switches. Junos OS Release 17.3R1 and later on EX9200 switches. Junos OS Release 19.1R1 and later on PTX10002 routers. Junos OS Evolved Release 20.2R1 and later on PTX10008 routers. UDP streaming is not supported over the management interface.

Table 140: resource statement Options *(Continued)*

resource string	Description	Release Information
/junos/npu-memory/	Sensor that exports both NPU memory statistics from the Packet Forwarding Engine and flow-label statistics from the Routing Engine. To export only flow-label statistics, include the `junos/npu-memory/flabel-memory/` resource string.	Junos OS Release 16.1R3 and later on PTX Series routers only. **NOTE**: Junos OS Release 17.2R1 and later on PTX1000 routers.
/junos/system/linecard/services/inline-jflow/	Packet Forwarding Engine sensor for performance metrics of the inline flow sampling process, such as the number of active flows and the number of exported flows.	Junos OS Release 16.1R3 and later on MX series and PTX series routers only. Junos OS Release and later on EX9200 switches, PTX1000 routers, and MX150 routers.
/junos/system/linecard/optics/	Packet Forwarding Engine sensor for various optical performance metrics, such as transmit and receive power levels.	Junos OS Release 17.1R1 and later. Junos OS Release and later 17.2R1 on QFX10000 switches. Junos OS Release 17.3R1 and later on EX9200 switches and PTX1000 routers.

Table 140: resource statement Options *(Continued)*

resource string	Description	Release Information
`/junos/system/linecard/packet/usage/`	Sensor for Packet Forwarding Engine error and drop statistics. Use these statistics to optimize traffic engineering and improve your network design. When you include the resource path `/junos/system/linecard/packet/usage/` in a subscription, statistics are streamed in the format: `/components/component[name='FPC0:NPU3']/properties/property[name='hwds-dlu-not-routable']/state/value`	Junos OS Release 22.1R1 and later on PTX1000 and PTX5000 routers and QFX10002-60C switches using Juniper proprietary gRPC.

Table 140: resource statement Options *(Continued)*

resource string	Description	Release Information

/junos/system/linecard/qmon/	Sensor for queue depth statistics for ingress and egress queue traffic. Statistics are exported directly from the line card.
	
	This sensor only supports single -streaming. Configuring this sensor to stream to multiple servers is not supported. If multiple servers are configured, no data is sent to any of the configured servers.
	
	The following example shows a configuration for single-streaming that will send data:
	
	`sensor qmon {`
	`server-name TEMP;`
	`export-name export-common;`
	`resource /junos/system/linecard/qmon/;`
	`}`
	
	The following example shows a multiple-server configuration that will not send data:
	
	`sensor qmon {`
	`server-name TEMP;`
	`server-name digi1;`
	`server-name digi2;`
	`export-name export-common;`
	`resource /junos/system/linecard/qmon/;`
	`}`
	
	NOTE: Issuing an operational `clear` command, such as `clear interfaces statistics all`, does not reset the statistics exported by the line card.
		Junos OS Release 17.1R1 and later on MX Series routers on MPC7E, MPC8E, and MPC9E only.
		
		Junos OS 17.3R1 and later on EX9200 switches.
		
		NOTE: virtual MX Series (vMX) routers are not supported.

Table 140: resource statement Options *(Continued)*

resource string	Description	Release Information
/junos/system/linecard/qmon-sw/	Sensor for congestion and latency monitoring statistics.	Junos OS Release 18.2R1 and later on QFX5100, QFX5110, and QFX5200 Switches Junos OS Release 18.3R1 and later on QFX5120-48Y and EX4650 Switches Junos OS Release 18.4R1 and later on EX4600 switches Junos OS Release 20.2R1 and later on EX3400 switches Junos OS Release 21.2R1 and later on PTX5000, PTX1000, PTX10002, PTX10008, and PTX10016 routers and QFX10002, QFX10008, and QFX10016 switches

Table 140: resource statement Options *(Continued)*

resource string	Description	Release Information
/junos/system/linecard/fabric/	Sensor for fabric statistics. The following types of statistics can be exported: • Fabric statistics for Packet Forwarding Engine pairs (`resource-filter` option is not supported) • FPC fabric statistics • Control Board and Switch Fabric Board fabric statistics.	Junos OS Release 17.2R1 and later on MX Series routers only. Junos OS Evolved Release 20.2R1 and later on PTX10008 routers. UDP streaming is not supported over the management interface. **NOTE**: virtual MX Series (vMX) routers are not supported.
/junos/system/linecard/packet/usage/	Sensor for Packet Forwarding Engine Statistics. This sensor exports statistics for counters and provides visibility into Packet Forwarding Engine error and drop statistics.	Junos OS Release 17.4R1 and later on MX Series and PTX Series routers

Table 140: resource statement Options *(Continued)*

resource string	Description	Release Information
/junos/services/segment-routing/interface/ingress/usage/ /junos/services/segment-routing/interface/egress/usage/ /junos/services/segment-routing/sid/usage/	Sensors for aggregate segment routing traffic with IS-IS. The first path exports inbound traffic. The second path exports outbound traffic. The third path exports inbound segment routing traffic for each segment identifier. **NOTE**: When you enable a sensor for segment routing statistics, you must also configure the `sensor-based-stats` statement at the `[edit protocols isis source-packet-routing]` hierarchy level. MX Series and PTX Series routers must also operate in enhanced mode. On MX Series routers, If not enabled by default, configure either the `enhanced-ip` statement or the `enhanced-ethernet` statement at the `[edit chassis network-services]` hierarchy level. On PTX Series routers, configure the `enhanced-mode` statement at the `[edit chassis network-services]` hierarchy level.	Junos OS Release 17.4 and later on MX Series and PTX5000 routers.
`/junos/system/subscriber-management/aaa/diameter/clients/gx`	Sensor for policy and charging rules function (PCRF) statistics for subscribers.	Junos OS Release 19.3R1 on MX5, MX10, MX40, MX150, MX204, MX240, MX480, MX960, MX2008, MX2010, MX2020, MX10003, MX10008, and MX100016 routers.

Table 140: resource statement Options *(Continued)*

resource string	Description	Release Information
`/junos/system/subscriber-management/aaa/diameter/clients/gy`	Sensor for Online Charging System (OCS) statistics for subscribers.	Junos OS Release 19.3R1 on MX5, MX10, MX40, MX150, MX204, MX240, MX480, MX960, MX2008, MX2010, MX2020, MX10003, MX10008, and MX100016 routers.
`/junos/system/subscriber-management/aaa/diameter/clients/nasreq`	Sensor for Network Access Server Application (NASREQ) statistics for subscribers.	Junos OS Release 19.3R1 on MX5, MX10, MX40, MX150, MX204, MX240, MX480, MX960, MX2008, MX2010, MX2020, MX10003, MX10008, and MX100016 routers.
`/junos/system/subscriber-management/aaa/diameter/peers/peer[peer_address='`*peer-address*`']/gx/response-time`	Diameter peer sensor that provides response time measurements for messages exchanged between an MX router and the peer for PCRF statistics. This sensor includes response-time and delay measurements in milliseconds. **NOTE**: The delay measurements are made over a 60-second measurement interval. As the reporting interval may be as much as 59 seconds out of phase with the measurement interval, the response time values may not be aligned with the reporting interval.	Junos OS Release 19.3R1 on MX5, MX10, MX40, MX150, MX204, MX240, MX480, MX960, MX2008, MX2010, MX2020, MX10003, MX10008, and MX100016 routers.

Table 140: resource statement Options *(Continued)*

resource string	Description	Release Information
`/junos/system/subscriber-management/aaa/diameter/peers/peer[peer_address='peer-address']/gy/response-time`	Diameter peer sensor that provides response time measurements for messages exchanged between an MX router and the peer for OCS statistics. This sensor includes response-time and delay measurements in milliseconds. **NOTE**: The delay measurements are made over a 60-second measurement interval. As the reporting interval may be as much as 59 seconds out of phase with the measurement interval, the response time values may not be aligned with the reporting interval.	Junos OS Release 19.3R1 on MX5, MX10, MX40, MX150, MX204, MX240, MX480, MX960, MX2008, MX2010, MX2020, MX10003, MX10008, and MX100016 routers.
`/junos/system/subscriber-management/aaa/diameter/peers/peer[peer_address='peer-address']/nasreq/response-time`	Diameter peer sensor that provides response time measurements for messages exchanged between an MX router and the peer for NASREQ statistics. This sensor includes response-time and delay measurements in milliseconds. **NOTE**: The delay measurements are made over a 60-second measurement interval. As the reporting interval may be as much as 59 seconds out of phase with the measurement interval, the response time values may not be aligned with the reporting interval.	Junos OS Release 19.3R1 on MX5, MX10, MX40, MX150, MX204, MX240, MX480, MX960, MX2008, MX2010, MX2020, MX10003, MX10008, and MX100016 routers.
`/junos/system/linecard/ddos/`	This PFE sensor exports the statistics of DDOS from MPC1, MPC2, MPC3, MPC5, MPC6, MPC7, MPC8, and MPC9 line cards.	Junos OS Release 21.1R1 on MX Series routers.
`/junos/system/linecard/page-drops/page-drop/`	Page drop statistics include page drop counter, interface and queue details.	Junos OS Evolved Release 22.3R1 on PTX10003 routers.

resource-filter *regular-expression*

(Optional) Specify a regular expression to filter data for a specific resource. For example, you can filter for a specific set of logical or physical interfaces, firewall filters, or LSP messages. When you configure a system resource to monitor and stream data globally—that is, systemwide—you do not need to include a regular expression.

Examples of regular expressions to filter data exported through sensor configuration:

- Logical interface statistics sensor—et-2/0/7:1*
- LSP events sensor—lsp-from-A-to-B*
- Firewall filter counters sensor—f_testl*

server-name [*streaming-server-names*]

Specify one or more servers to transport data for collection. Include at least one server-name configured at the [`edit services analytics streaming-server` *`server-name`*] hierarchy level.

> **NOTE**: Starting in Junos OS Release 15.1F6, you can configure as many as four streaming servers for a single sensor configuration. In previous releases, you can specify only one streaming server for each configured sensor. To specify more than one streaming server for a sensor, you must enclose the names in brackets.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 15.1F3.

Support for MPC7E, MPC8E, and MPC9E on MX Series routers added in Junos OS Release 15.1F5.

Support for FPC1 and FPC2 on PTX Series routers added in Junos OS Release 16.1R3.

Statement introduced in Junos OS Release 19.1R1 for PTX3000 routers and PTX5000 routers with FPC2.

Change History Table

Feature support is determined by the platform and release you are using. Use Feature Explorer to determine if a feature is supported on your platform.

Release	Description
19.1R1	Statement introduced in Junos OS Release 19.1R1 for PTX3000 routers and PTX5000 routers with FPC2.

RELATED DOCUMENTATION

export-profile (Junos Telemetry Interface) | 6669

separator

IN THIS SECTION

- Syntax | 16593
- Hierarchy Level | 16593
- Description | 16593
- Options | 16594
- Required Privilege Level | 16594
- Release Information | 16594

Syntax

```
separator special-character;
```

Hierarchy Level

```
[edit access profile profile-name client-name-filter client-name]
```

Description

Specify a character to identify where stripping of characters occurs in a client name. Stripping removes characters to the right of each instance of the specified character, plus the character itself. The stripping begins with the rightmost separator character.

Use the `separator` statement with the `count` statement to determine which characters in a client name are stripped. If the specified number of separator characters (count) exceeds the actual number of separator characters in the client name, stripping stops at the last available separator character.

Options

special-character—Character used to identify where to start the stripping of characters in a client name.

Required Privilege Level

access—To view this statement in the configuration.

access-control—To add this statement to the configuration.

Release Information

Statement introduced in Release 8.5 of Junos OS.

Obtaining Username and Role Information Through Firewall Authentication

seq-number-validated

IN THIS SECTION

- Syntax | 16594
- Hierarchy Level | 16595
- Description | 16595
- Required Privilege Level | 16595
- Release Information | 16595

Syntax

```
seq-number-validated;
```

Hierarchy Level

```
[edit security gtp profile profile-name]
```

Description

When the command seq-number-validated is configured, GTP ALG check the sequence number in the GTP-U packet. If it is not configured, the sequence check is disabled by default.

From Junos OS Release 20.4R1 onwards, the `[edit security gprs gtp profile profile-name]` hierarchy level is replaced by `[edit security gtp profile profile-name]`.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.1X45-D10.

sequence-check-required

IN THIS SECTION

- Syntax | 16596
- Hierarchy Level | 16596
- Description | 16596
- Required Privilege Level | 16596
- Release Information | 16596

Syntax

```
sequence-check-required;
```

Hierarchy Level

```
[edit security policies from-zone zone-name to-zone zone-name policy policy-name then permit tcp-
options]
```

Description

Enable sequence check per policy. The sequence-check-required value overrides the global value no-sequence-check.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.4.

sequence-number (Security IDP ICMP Headers)

IN THIS SECTION

- Syntax | 16597
- Hierarchy Level | 16597
- Description | 16597
- Options | 16597
- Required Privilege Level | 16598
- Release Information | 16598

Syntax

```
sequence-number {
    match (equal | greater-than | less-than | not-equal);
    value sequence-number;
}
```

Hierarchy Level

```
[edit security idp custom-attack attack-name attack-type signature protocol icmp],

[edit security idp custom-attack attack-name attack-type signature protocol icmpv6]
```

Description

Specify the sequence number of the packet. This number identifies the location of the request/reply in relation to the entire sequence.

Options

- `match` (`equal` | `greater-than` | `less-than` | `not-equal`)—Match an operand.
- `value` *`sequence-number`*—Match a decimal value.

- **Range:** 0 through 65,535

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.3. Statement modified in Junos OS Release 12.3X48-D25 to add ICMPv6 protocol support.

sequence-number (Security IDP TCP Headers)

IN THIS SECTION

- Syntax | 16598
- Hierarchy Level | 16599
- Description | 16599
- Options | 16599
- Required Privilege Level | 16599
- Release Information | 16599

Syntax

```
sequence-number {
    match (equal | greater-than | less-than | not-equal);
    value sequence-number;
}
```

Hierarchy Level

```
[edit security idp custom-attack attack-name attack-type signature protocol tcp]
```

Description

Specify the sequence number of the packet. This number identifies the location of the data in relation to the entire data sequence.

Options

- `match` (`equal` | `greater-than` | `less-than` | `not-equal`)—Match an operand.
- `value` *`sequence-number`*—Match a decimal value.
- **Range:** 0 through 4,294,967,295

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.3.

serial-number

IN THIS SECTION

- Syntax | 16600
- Hierarchy Level | 16600
- Description | 16600
- Options | 16600
- Required Privilege Level | 16600

Release Information | 16600

Syntax

```
serial-number serial-number;
```

Hierarchy Level

```
[edit virtual-chassis member member-id]
```

Description

In a preprovisioned Virtual Chassis or Virtual Chassis Fabric (VCF), specify the serial number of each member switch to be included in the configuration. If you do not include the serial number within the configuration, the switch cannot be recognized as a member of a preprovisioned configuration. Serial number values are case-sensitive.

In an EX8200 Virtual Chassis configuration, specify the serial number of each XRE200 External Routing Engine and each EX8200 member switch to be included in the Virtual Chassis configuration. If you do not include the serial number within the Virtual Chassis configuration, the external Routing Engine or switch cannot be recognized as a member of the configuration.

Options

serial-number—Permanent serial number for the external Routing Engine or for the member switch.

Required Privilege Level

system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.0.

serial-number (Junos Fusion)

IN THIS SECTION

- Syntax | **16601**
- Hierarchy Level | **16601**
- Description | **16602**
- Default | **16602**
- Options | **16602**
- Required Privilege Level | **16602**
- Release Information | **16602**

Syntax

```
serial-number serial-number;
```

Hierarchy Level

```
[edit chassis satellite-management fpc slot-id]
```

Description

Bind the specified FPC slot ID to a satellite device based on the serial number.

A Junos Fusion provides two methods of assigning an FPC identifier: Unique ID-based FPC identification and connectivity-based FPC identification. Unique ID-based FPC identification maps an FPC slot ID to a satellite device's MAC address or serial number, while unique ID-based FPC identification maps an FPC slot ID to a cascade port. This statement is used to assign an FPC ID using unique ID-based FPC identification by mapping the FPC slot ID to the satellite device's serial number.

In a Junos Fusion, each satellite device must be mapped to an FPC identifier (FPC ID). The FPC ID is used for Junos Fusion configuration, monitoring, and maintenance. Interface names—which are identified using the *type-fpc* / *pic* / *port* format—use the FPC ID as the *fpc* variable when the satellite device is participating in a Junos Fusion. For instance, built-in port 2—a Gigabit Ethernet interface on a satellite device that is using 101 as its FPC ID—uses ge-101/0/2 as its interface name.

For additional information on the role of FPC slot IDs in a Junos Fusion, see Understanding Junos Fusion Enterprise Components or *Understanding Junos Fusion Provider Edge Components*.

If the serial number that is configured using this statement does not match the serial number of the satellite device, the device is not converted into a satellite device.

Default

No FPC slot IDs are associated with satellite devices, by default.

Options

serial-number Specifies the serial number of the satellite device.

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 14.2R3.

Statement introdcued in Junos OS Release 16.1R1 for Junos Fusion Enterprise.

serial-number (MX Series Virtual Chassis)

IN THIS SECTION

- Syntax | 16603
- Hierarchy Level | 16603
- Description | 16603
- Options | 16604
- Required Privilege Level | 16604
- Release Information | 16604

Syntax

```
serial-number serial-number;
```

Hierarchy Level

```
[edit virtual-chassis member member-id]
```

Description

As part of the preprovisioned configuration for an MX Series Virtual Chassis, specify the chassis serial number of each MX Series member router in the Virtual Chassis configuration. If you do not correctly specify a router's serial number in the preprovisioned configuration, the software does not recognize that router as a member of the Virtual Chassis.

Options

serial-number—Alphanumeric string that represents the chassis serial number of each member router in the Virtual Chassis configuration. The chassis serial number is located on a label affixed to the side of the MX Series chassis. You can also obtain the router's chassis serial number by issuing the `show chassis hardware` command.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.2.

    }
}
```

Hierarchy Level

[edit]

Description

Applicable only to Junos node slicing set up using external server model.

Configure the server interfaces for the JDM and GNFs. These include a JDM management interface, a GNF management interface, and two server interfaces that are connected to the MX Series router.

Options

cb0 *cb0-interface*	The server interface that is connected to the control board 0 of the MX Series router.
cb1 *cb1-interface*	The server interface that is connected to the control board 1 of the MX Series router.
jdm-management *jdm-management-interface*	The server interface to be used as the JDM management interface.
vnf-management *gnf-management-interface*	The server interface to be used as GNF management interface.

Syntax

```
server-cluster {
    ike-gateway gateway-name;
    retransmission-period seconds;
    server-role (root-server | sub-server);
}
```

Hierarchy Level

```
[edit security group-vpn server group name]
```

Description

Configure the Group Domain of Interpretation (GDOI) group controller/key server (GCKS) cluster for the specified group. All servers in a group VPN server cluster must be SRX Series Firewalls.

Options

ike-gateway ***gateway-name***

(Required) Specify the name of the IKE gateway for the local device in the group server cluster. IKE gateways are configured at the [`edit security group-vpn server ike`] hierarchy level.

If the local device is a root-server, the IKE gateway name must be a sub-server in the cluster; up to four sub-server IKE gateways can be specified.

If the local device is a sub-server, the IKE gateway name must be the root-server.

retransmission-period ***seconds***

(Optional) Specify the time after which the root-server retransmits a `cluster-update` message if it has not received an acknowledgement from a sub-server.

- **Range:** 2 to 60 seconds.
- **Default:** 10 seconds.

server-role

(Required) Assign the role of the local device in the group server cluster, either `root-server` or `sub-server`. Only one device in the cluster can be configured as the root-server. You can configure up to four other devices as a sub-server in a group server cluster.

You must ensure that there is only one root-server at any time for a group VPN server cluster.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

    routing-instance [ <default> routing-instance-names ];
}
```

Hierarchy Level

```
[edit forwarding-options helpers bootp],
[edit forwarding-options helpers bootp interface (interface-name | interface-group)]
```

Description

Configure the router or switch to act as a DHCP and BOOTP relay agent. The device forwards all broacast requests within the configured subnet to all configured servers in parallel. To support clients on different VRFs, see the "relay-agent-option" on page 14279 statement.

Options

- *address*—One or more addresses of the server.
- `logical-system` *logical-system-name*—(Optional) Logical system of the server.

- `routing-instance` *routing-instance-names*—(Optional) Routing instance name that belong to the DHCP or BOOTP relay agent.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Syntax

```
server address <logical-system logical-system-name> <routing-instance routing-instance-name>;
```

Hierarchy Level

```
[edit forwarding-options helpers domain],
[edit forwarding-options helpers domain interface interface-name],
[edit forwarding-options helpers port port-number],
[edit forwarding-options helpers port port-number interface interface-name],
[edit forwarding-options helpers tftp],
[edit forwarding-options helpers tftp interface interface-name]
```

Description

Specify the DNS or TFTP server for forwarding DNS or TFTP requests, or specify a destination server address for forwarding LAN broadcast packets as unicast traffic for a custom-configured UDP port.

When configuring port helpers, in releases prior to Junos OS Release 17.2, only one server can be specified for a given port. For Junos OS Release 17.2 and later, multiple servers can be specified for a given port at the global or interface-specific level. When multiple servers are specified, the same packet, with the originator IP address and port requests, is forwarded to the different configured servers; the payload of the UDP packet is not modified.

Options

address—IP address of the server.

logical-system ***logical-system-name***—(Optional) Logical system name of the server.

routing-instance [***routing-instance-names*** **]**—(Optional) Set the routing instance name or names that belong to the DNS server or TFTP server.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Statement introduced for port helpers in Junos OS Release 17.2R1 for EX4300 switches.

Support for multiple server instances for a given port introduced in Junos OS Release 17.2 for MX Series routers.

Support for multiple server instances for a given port introduced in Junos OS Release 17.3R1 for EX9200 switches.

server-duid-type (DHCP Local Server)

IN THIS SECTION

- Syntax | 16626
- Hierarchy Level | 16626
- Description | 16626
- Options | 16627
- Required Privilege Level | 16627
- Release Information | 16627

Syntax

```
server-duid-type type;
```

Hierarchy Level

```
[edit system services dhcp-local-server dhcpv6]
```

Description

Configure the DHCP Unique Identifier (DUID) type that the DHCPv6 server supports. The server uses the DUID to identify clients for configuration and to group clients into identity associations.

Use this statement to explicitly configure the DUID-LL type. DUID-LL uses a link-layer network interface address on the device as part of the unique identifier. Remove this configuration to return to the default type, DUID-EN. DUID-EN has a vendor-assigned value based on the vendor's enterprise number and an IANA-recognized hardware type code. DUID-EN is not explicitly configurable.

NOTE: The DUID-LLT type is not supported.

Options

type DUID type to support. The only available option is `duid-ll`.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 16.1.

server (Easy EVPN LAG Configuration)

IN THIS SECTION

Syntax | 16629

- Hierarchy Level | 16629
- Description | 16629
- Options | 16630
- Required Privilege Level | 16633
- Release Information | 16633

Syntax

```
server name {
  apply-config-groups config-groups;
  enable-pxe-boot;
  esi-lag-id esi-lag-id;
  interface [ interface ... ];
  mac-vrf-instance instance-id {
      vlan-id-list [ vlan-id-list ... ]
  };
  single-home-id single-home-id;
  vlan-id-list [ vlan-id-list ... ]);
};
```

Hierarchy Level

```
[edit services evpn evpn-vxlan]
```

Description

Specify parameters to generate the configuration statements for servers connected to a provider edge (PE) device in an Ethernet VPN (EVPN) fabric with Virtual Extensible LAN (VXLAN) encapsulation.

The server might be a customer edge (CE) device or end server connected to the EVPN PE device, and can be:

- Single-homed to the PE device.
- Multihomed on an Ethernet segment (identified by an Ethernet segment identifier [ESI]) in a link aggregation group (LAG) to the PE device and a peer PE device in the EVPN fabric.

> **NOTE**: We refer to this type of multihomed Ethernet segment connection as an *ESI LAG*.

You use statements at the `[edit services evpn]` hierarchy level to simplify configuring an EVPN fabric with ESI LAGs in the topology. The feature you enable with statements in this hierarchy is an easy EVPN LAG configuration feature, also called EZ-LAG.

You only need to configure a few statements to provide the parameters required for an EVPN core fabric with multihomed or single-homed customer edge (CE) devices (or end server devices). When you commit the `[edit services evpn]` configuration statements, the device uses a commit script to generate the corresponding standard EVPN fabric configuration statements.

The statements at the `[edit services evpn evpn-vxlan server]` hierarchy level provide the parameters the commit script needs to generate a default configuration for the peer PE to server connections, including configuration for:

- Multihomed server Etehrnet segments, ESI LAG interfaces and member VLANs
- Single-homed server interfaces and member VLANs
- Lightweight leaf to server loop detection on interfaces connecting PE leaf devices to servers

  > **NOTE**: To disable generation of the loop detection configuration statements, you can configure the `no-loop-detect-config` option at the `[edit service evpn defaults-override]` hierarchy level.

- Storm control on PE to server interfaces

  > **NOTE**: To disable generation of the storm control configuration statements, you can configure the `no-storm-control-config` option at the `[edit service evpn defaults-override]` hierarchy level.

Options

(Required) ***name***	Specify a name to identify a server connected to the peer PE device. For example, SERVER_1 or hostA.
apply-config-groups ***config-groups***	Apply the specified configuration groups to the configuration for the server aggregated Ethernet interface bundles that the commit script generates from the statements for this server.

enable-pxe-boot

Enable this connected server to use a preboot execution environment (PXE) boot process.

When you set this option set, the commit script configures LACP `force-up` status on the link to the server. That status ensures the link is UP when the server boots up, which the PXE boot process requires. See *Aggregated Ethernet Interfaces* for more on the LACP `force-up` option and forcing LAG links or interfaces with limited LACP capacity to be up.

(Required) esi-lag-id *esi-lag-id*

Assign an ESI LAG connection ID for this server. With this option, the commit script generates the configuration statements for an ESI LAG connection from the PE device to this multihomed server.

The commit script assigns aggregated Ethernet interfaces (ae*X*) on the peer PE device for ESI LAG connected servers starting with the base number 0. The commit script adds the *esi-lag-id* value to that base. For example, if you configure *esi-lag-id* = 2 for this server, the generated configuration uses interface name ae2.

> **NOTE**: The commit script uses ae0 for the peer to peer PE devices connections, so ae0 is never assigned as a PE-device-to-server ESI LAG interface.

You must configure this option or the `single-home-id` option for each connected server.

- **Range for *esi-lag-id***: 1 through 1024 (which generates interface names ae1 through ae1024)

(Required) interface [*interface-name* ...];

Specify the interface name for the physical link or links from the peer PE device to this multihomed or single-homed server.

Use this option with the `esi-lag-id` option or the `single-home-id` option that identifies this connected server.

mac-vrf-instance *instance-id*

Specify a MAC-VRF instance identifier that hosts this server.

By default, if you don't configure this statement, the commit script generates the configuration for one MAC-VRF instance with 1 as the default MAC-VRF *instance-id*.

If you include the `vlan-id-list` *`vlan-id-list`* option with this statement, the commit script generates configuration statements that associate this MAC-VRF instance with the listed server VLANs.

> **NOTE**: If you don't configure the `mac-vrf-instance` statement, you must configure the `vlan-id-list` *`vlan-id-list`* statement at the `[edit services evpn evpn-vxlan server` *`name`*`]` hierarchy level with at least one member VLAN. The commit script generates configuration statements that associate that list of VLANs with the default MAC-VRF instance (which has *instance-id* 1 and instance name __SERVICES_EVPN_EVPN_VXLAN_MAC_VRF_1).

See the description for the `vlan-id-list` option below for details on how to specify the list of VLAN IDs.

- **Range for *instance-id*:** 1 through 255

(Required) single-home-id *single-home-id*

Assign a single-homed connection ID for this server. With this option, the commit script generates the configuration statements for a connection from the PE device to this single-homed server.

The commit script assigns aggregated Ethernet interface names on the peer PE device for single-homed server connections. The highest `esi-lag-id` index for interfaces to multihomed servers is 1024, which corresponds to interface name ae1024. So to assign interface names for links to single-homed servers, the commit script adds the *single-home-id* value to the base number 1024. As a result, single-homed server interface names start with ae1025 for *single-home-id* = 1 . If you configure *single-home-id* = 2, the generated configuration uses interface name ae1026, and so on.

You must configure this option or the `esi-lag-id` option for each connected server.

- **Range for *single-home-id*:** 1 through 1024 (which generates interface names ae1025 through ae2048)

vlan-id-list [*vlan-id-number* ...]

(Required) List the VLANs this server hosts. Specify one or more VLANs by VLAN ID number. Use spaces to separate multiple individual VLAN IDs (such as [100 200], or use a dash to indicate a contiguous range of VLAN IDs (such as [100-300]). The commit script generates the statements that configure the specified VLANs.

You must configure at least one VLAN ID list for each server. You can configure the server's `vlan-id-list` statement at either of the following hierarchy levels:

- `[edit services evpn evpn-vxlan server` *`name`* `mac-vrf-instance` *`instance-id`*`]`—Associate the listed VLANs with the MAC-VRF instance for the specified instance ID in the generated configuration .

- [edit services evpn evpn-vxlan server *name*]—Associate the listed VLANs with:
  - The default MAC-VRF instance ID, which is 1. The commit script uses MAC-VRF instance ID 1 when you don't specify any mac-vrf-instance statements for this server.
  - All MAC-VRF instance IDs that you configure using the mac-vrf-instance statement for this server.
- **Range for *vlan-id-number* values:** 1 through 4094

See CLI Explorer.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 23.2R1 and Junos OS Evolved Release 23.2R1.

[edit routing-instances routing-instance-name forwarding-options dhcp-relay dhcpv6]
```

Description

Specify the name of a group of DHCP server addresses for use by the extended DHCP relay agent. Apply the group with the `active-server-group` statement globally for all interfaces or for a named group of interfaces configured with the `group` statement. This mechanism enables you to apply different DHCP relay configurations for different groups of servers, with a common configuration for the servers within a server group.

Options

server-group-name Name of the group of DHCP or DHCPv6 server addresses.

server-ip-address IP address of the DHCP server belonging to this named server group. Use IPv6 addresses when configuring DHCPv6 support. Starting in Junos OS Release 18.4R1, you can configure up to 32 server IP addresses per group for DHCPv4 servers. In earlier releases, you can configure only up to 5 server IP addresses for DHCPv4 servers. For DHCPv6

servers, you can configure only up to 32 addresses in all releases. The configuration fails commit check if you configure more than the maximum number of server addresses.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 8.3.

Support at the `[edit ... dhcpv6]` hierarchy levels introduced in Junos OS Release 11.4.

}
```

Hierarchy Level

```
[edit services icap-redirect profile name],
[edit logical-systems logical-system-name services icap-redirect profile name]
```

Description

Configure the ICAP server details.

When you configure the ICAP redirect service on SRX Series Firewalls, you must configure the ICAP server details. ICAP server configuration allows you to define the settings required to process request messages, response messages, authorization, and so on. You can also specify an SSL profile in the ICAP server configuration that enables you to secure the connection to the ICAP server.

You can configure up to two ICAP servers.

Options

name ICAP server name.

host ICAP server hostname or IP address.

port ICAP server listening port, default port is reached according to the protocol defined.

- **Default:** 1344
- **Range:** 1025 through 65535

route-instance Virtual router that is used for launching the service.

reqmod-uri Path to the service that handles Request Modification (REQMOD) requests.

respmod-uri Path to the service that handles Response Modification (RESPMOD) requests.

sockets Number of connections to create the ICAP service.

- **Default:** 8
- **Range:** 1 through 64

tls-profile SSL profile configured to provide a secure connection to the ICAP server.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

system

Release Information

[edit routing-instances routing-instance-name forwarding-options dhcp-relay relay-option-82],
[edit routing-instances routing-instance-name forwarding-options dhcp-relay group group-name
relay-option-82]
```

Description

Add the suboptions `link-selection` and `server-id override` to option-82 information for DHCP packets relayed to the server.

In network configurations where a firewall on the broadband network gateway (BNG) is between the DHCPv4 relay agent and the DHCP server, only the BNG loopback address passes through the BNG firewall. In that case, DHCP unicast packets do not pass through the firewall and and discarded. To enable DHCP unicast packets to pass through the BNG firewall, use the `relay-source` configuration statement to configure the DHCP relay agent to use the loopback address as the source address in IP headers and DHCP messages. In this case, this configuration statement adds the `link-selection` suboption

to provide the DHCP server information to locate the correct address pool for the DHCP client and adds the `server-id override` suboption to set the server ID option.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

server-identifier

IN THIS SECTION

- Syntax | 16639
- Hierarchy Level | 16640
- Description | 16640
- Default | 16640
- Options | 16640
- Required Privilege Level | 16640
- Release Information | 16640

Syntax

```
server-identifier address;
```

Hierarchy Level

```
[edit system services dhcp],
[edit system services dhcp pool],
[edit system services dhcp static-binding]
```

Description

Configure a server identifier. The identifier can be used to identify a DHCP server in a DHCP message. It can also be used as a destination address from clients to servers (for example, when the boot file is set, but not the boot server).

Servers include the server identifier in **DHCPOFFER** messages so that clients can distinguish between multiple lease offers. Clients include the server identifier in **DHCPREQUEST** messages to select a lease and indicate which offer is accepted from multiple lease offers. Also, clients can use the server identifier to send unicast request messages to specific DHCP servers to renew a current lease.

This address must be a manually assigned, static IP address. The server cannot send a request and receive an IP address from itself or another DHCP server.

Default

If no server identifier is set, the DHCP server sets the server identifier based on the primary interface address used by the server to receive a client request. For example, if the client sends a DHCP request and the server receives it on `fe-0/0/0` and the primary interface address is `10.1.1.1`, then the server identifier is set to `10.1.1.1`.

Options

address—IPv4 address of the server. This address must be accessible by all clients served within a specified range of addresses (based on an address pool or static binding).

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

server-member-communication (Security Group VPN Server)

IN THIS SECTION

- Syntax | 16646
- Hierarchy Level | 16647
- Description | 16647
- Options | 16647
- Required Privilege Level | 16647
- Release Information | 16648

Syntax

```
server-member-communication {
    certificate certificate-id;
    communication-type (unicast);
    encryption-algorithm (aes-128-cbc | aes-192-cbc | aes-256-cbc);
    lifetime-seconds seconds;
    number-of-retransmission number;
    retransmission-period seconds;
    sig-hash-algorithm (sha-256 | sha-384);
}
```

Hierarchy Level

```
[edit security group-vpn server group name]
```

Description

Enable and configure server to member communication. When these options are configured, group members receive new keys before current keys expire. Starting with Junos OS Release 15.1X49-D80, the minimum value that you can configure for the `lifetime-seconds` option is 300 seconds instead of 180 seconds.

Options

- `certificate` *`certificate-id`*—Specify the certificate identification. Only RSA keys are supported.
- `communication-type`—Configure `unicast` (the default).
- `encryption-algorithm`—Encryption used for communications between the group server and group member. Specify `aes-128-cbc`, `aes-192-cbc`, or `aes-256-cbc`.
- `lifetime-seconds` *`seconds`*—Lifetime, in seconds, of the key encryption key (KEK). Specify a value from 300 to 86,400. The default is 3600 seconds.
- `number-of-retransmission` *`number`*—For unicast communications, the number of times the group server retransmits messages to a group member when there is no reply. Specify a value from 0 to 60. The default is 2.
- `retransmission-period` *`seconds`*—The time period between a transmission and the first retransmission when there is no reply from the group member. Specify a value from 2 to 60. The default is 10 seconds.
- `sig-hash-algorithm`—Authentication algorithm used to authenticate the group member to the group server. Specify `sha-256` or `sha-384`.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Group VPNv2 Overview

group (Security Group VPN) | 7894

server (NTP)

IN THIS SECTION

- Syntax | 16648
- Hierarchy Level | 16649
- Description | 16649
- Options | 16649
- Required Privilege Level | 16650
- Release Information | 16650

Syntax

```
server address {
    key key;
    nts remote-identity {
      hostname hostname;
      distinguished-name(container container | wildcard wildcard);
       }
    prefer;
    routing-instance routing-instance;
    version version;
}
```

Hierarchy Level

```
[edit system ntp]
```

Description

For NTP, configure the local router or switch to operate in client mode with the remote system at the specified *address*. In this mode, the local router or switch can be synchronized with the remote system, but the remote system can never be synchronized with the local router or switch.

If the NTP client time drifts so that the difference in time from the NTP server exceeds 128 milliseconds, the client is automatically stepped back into synchronization. If the offset between the NTP client and server exceeds the 1000-second threshold, the client still synchronizes with the server, but it also generates a system log message noting that the threshold was exceeded.

Options

address Address of the remote system. You must specify an address, not a hostname.

key *key-number* (Optional) Use the specified key number to encrypt authentication fields in all packets sent to the specified address.

- **Range:** Any unsigned 32-bit integer

nts Enables Network Time Security (NTS), which uses Transport Layer Security (TLS) protocol and Authenticated Encryption with Associated Data (AEAD) to obtain network time in an authenticated manner to the users. Specified server must also support the NTS feature when you enable NTS on a client device.

remote-identity (Optional) Configure the options to verify the NTS enabled server's identity.

hostname *hostname* (Optional) Specify the fully qualified domain name (FDQN) of the server. This hostname should match with the FQDN of the server in its local certificate's **Subject Alternative Name** field.

distinguished-name (container *container* | wildcard *wildcard*) (Optional) You can verify the identity of NTS-enabled server by its distinguished name in the server certificate.

container *container*
: If you use the *container* option, the order of the fields in the `distinguished-name` and their values must exactly match with the values in the server certificate.

wildcard *wildcard*
: If you use the *wildcard* option, the order of the fields in the `distinguished-name` does not matter.

prefer
: (Optional) Mark the remote system as preferred host, which means that if all other things are equal, this remote system is chosen for synchronization among a set of correctly operating systems.

routing-instance *routing-instance*
: (Optional) Routing instance through which the server is reachable.

> **NOTE**: You can use the routing instance name `mgmt_junos` to enable access to NTP servers through the management interface.

When configuring the NTP service in the management VRF (`mgmt_junos`), you must configure at least one IP address on a physical or logical interface within the default routing instance and ensure that this interface is up in order for the NTP service to work with the mgmt_junos VRF.

version *value*
: (Optional) Specify the version number to be used in outgoing NTP packets.

- **Range:** 1 through 4
- **Default:** 4

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

}
```

Hierarchy Level

```
[edit services pcp]
```

Description

Configure PCP server options. PCP enables hosts to operate servers for a long time (as in the case of a webcam) or a short time (for example, while playing a game or on a phone call) when behind a NAT device, including when behind a carrier-grade NAT operated by their ISP. PCP enables applications to create mappings from an external IP address and port to an internal IP address and port.

PCP is supported on the MS-DPC, MS-100, MS-400, and MS-500 MultiServices PICS. Starting in Junos OS Release 17.4R1, PCP is also supported on the MS-MPC and MS-MIC. Starting in Junos OS Release 20.1R1, PCP is also supported for Next Gen Services.

Options

ipv4-address IPv4 address of the PCP server.

ipv6-address IPv6 address of the PCP server.

long-lifetime-error Time limit for generating long lifetime errors.

- **Default:** 1800 seconds
- **Range:** 900 through 18,000 seconds

mapping-lifetime-max Maximum lifetime, in seconds, for PCP mapping. If the PCP client requests a lifetime less than the maximum configured, the server will assign the maximum lifetime and respond accordingly.

- **Default:** 86,400 seconds
- **Range:** 3600 through 4294667 seconds

mapping-lifetime-min Minimum lifetime, in seconds, for PCP mapping. If a PCP client requests a lifetime less than the minimum configured, the server will assign a minimum lifetime and respond accordingly.

- **Default:** 300 seconds
- **Range:** 120 through 3600 seconds

max-mappings-per-client Maximum number of PCP mappings that the PCP client can request.

- **Default:** 32
- **Range:** 1 through 32

pool-name	Name of the NAT pool to use for PCP mapping. You can identify multiple pools. If you do not specify a NAT pool for mapping, the Junos OS performs a partial rule match based on the source IP, source port, and protocol, and the Junos OS uses the NAT pool configured for the first matching rule to allocate mappings for PCP.
prefer-failure	Generate an error message when the PCP client requests a specific IP address or port that is not available, rather than assigning another available address from the NAT pool.
short-lifetime-error	Time limit for generating short lifetime errors. • **Default:** 30 seconds • **Range:** 15 through 300 seconds
softwire-concentrator-name	Softwire concentrator name whose softwire-address is used in creating PCP mappings. The PCP server address must be the same as the softwire-concentrator address.
third-party	Enable third-party requests by the PCP client.

The other statements are explained separately.

Required Privilege Level

Configuring Active Flow Monitoring on PTX Series Packet Transport Routers

server (RADIUS Accounting)

IN THIS SECTION

- Syntax | 16657
- Hierarchy Level | 16657
- Description | 16657
- Options | 16657
- Required Privilege Level | 16659
- Release Information | 16659

Syntax

```
server {
    server-address {
        accounting-port port-number;
        accounting-retry number;
        accounting-timeout seconds;
        dynamic-request-port number;
        max-outstanding-requests value;
        port number;
        preauthentication-port number;
        preauthentication-secret secret;
        retry number;
        routing-instance routing-instance-name;
        secret password;
        source-addresssource-address;
        timeout seconds;
    }
```

Hierarchy Level

```
[edit system accounting destination radius]
```

Description

Configure RADIUS accounting.

To configure multiple RADIUS accounting servers, include multiple `server` *server-address* statements. The servers are tried in order and in a round-robin fashion until a valid response is received from one of the servers or until all the configured retry limits are reached.

NOTE: The `[edit system accounting]` hierarchy is not available on QFabric systems.

Options

server-address Specify the IPv4 or IPv6 address of the RADIUS authentication server.

accounting-port *port-number*

Configure the accounting port number on which to contact the RADIUS server.

- **Range:** 1 through 65,335
- **Default:** 1813

accounting-retry *number*

Configure the number of accounting retry attempts.

- **Range:** 0 through 100 attempts
- **Default:** 0

accounting-timeout *seconds*

Configure the accounting request timeout period.

- **Range:** 0 through 1000 seconds
- **Default:** 0

dynamic-request-port *number*

Configure the RADIUS client dynamic request port number

- **Range:** 1 through 65535
- **Default:** 3799

max-outstanding-requests *value*

Configure the maximum number of outstanding requests in flight to the server.

- **Range:** 0 through 2000 requests
- **Default:** 1000 requests

port *port-number*

Configure the port number on which to contact the RADIUS server.

- **Range:** 1 through 65,335
- **Default:** 1812 (as specified in RFC 2865)

preauthentication-port *number*

Configure the RADIUS server preauthentication-port number.

- **Range:** 1 through 65535

preauthentication-secret *secret*

Configure the shared secret with the RADIUS server; it can include spaces if the character string is enclosed in quotation marks. The secret used by the local device must match that used by the RADIUS server.

retry *value*

Configure the number of times that the device is allowed to try to contact a RADIUS authentication server.

- **Range:** 1 through 100
- **Default:** 3

routing-instance *routing-instance-name*

Configure the routing instance name for the management routing instance. In the case of configuring the non-default management instance, use the value `mgmt_junos`. that is `mgmt_junos`. Configuring this option along with the `management-instance` statement enables authentication processes (for example, RADIUS and TACACS+) to use the non-default management routing instance for packet traffic.

> **NOTE**: You must also define the mgmt_junos routing instance under the `[edit routing-instances]` hierarchy level.

If you do not configure the mgmt_junos instance under the `[edit routing-instances]` hierarchy level and configure it only under `tacplus-server` or `radius-server`, the commit will fail.

secret *password*

(Required) Configure the password (shared secret) to use with the RADIUS server; it can include spaces if the character string is enclosed in quotation marks. The secret password used by the local device must match that used by the RADIUS server.

source-address *source-address*

Configure a valid IPv4 or IPv6 address configured on one of the device's interfaces.

timeout *seconds*

Configure the amount of time the local device waits to receive a response from a RADIUS server.

- **Range:** 1 through 1000 seconds
- **Default:** 3 seconds

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 7.4.

`routing-instance` introduced in Junos OS Release 18.1R1.

server-reject-bridge-domain | server-reject-vlan

IN THIS SECTION

- Syntax | **16662**
- Hierarchy Level | **16662**

- Description | 16662
- Default | 16662
- Options | 16663
- Required Privilege Level | 16663
- Release Information | 16663

Syntax

```
(server-reject-bridge-domain bridge-domain | server-reject-vlan (vlan-id | vlan-name))  {
    block-interval block-interval;
    eapol-block;
    gbp-tag gbp-tag
}
```

Hierarchy Level

```
[edit logical-systems name protocols              dot1x              authenticator
interface (all | [interface-names])],
[edit protocols dot1x                 authenticator interface (all | [interface-names])]
```

Description

For a device configured for 802.1X authentication, specify that when the device receives an Extensible Authentication Protocol Over LAN (EAPoL) Access-Reject message during the authentication process between the device and the RADIUS authentication server, supplicants attempting to access the LAN are granted access and moved to a specific bridge domain or VLAN. Any bridge domain, VLAN name or VLAN ID sent by a RADIUS server as part of the EAPoL Access-Reject message is ignored.

When you specify the bridge domain, VLAN ID, VLAN name, or GBP-tag, bridge domain or VLAN must already be configured on the device.

Default

None

Options

server-reject-bridge-domain *bridge-domain*
(MX Series only) Move the supplicant on the interface to the bridge domain specified by this name or numeric identifier.

server-reject-vlan (*vlan-id* **|** *vlan-name*
(MX Series in enhanced LAN mode, EX, QFX, and SRX Series only) Move the supplicant on the interface to the VLAN specified by this name or numeric identifier.

block-interval *seconds*
Specify the number of seconds that the 802.1X interface ignores Extensible Authentication Protocol (EAP) start messages from the client when an EAPoL block has been enabled on the 802.1X interface.

- **Range:** 120 through 65,535 seconds

gbp-tag *gbp-tag*
Specify the GBP tag to apply when RADIUS rejects the client authentication. If you configure the `gbp-tag` *gbp-tag* and the client authenticates in `server-reject vlan`, then the configured `gbp-tag` filter is also installed for the client. You can only configure the `server-reject gbp-tag` *gbp-tag* when the `server-reject-vlan` *vlan-id* option is configured.

- **Range:** 1 through 65,535

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Release Information

`gbp-tag` *gbp-tag* `introduced in Junos OS Release 23.4R1 for EX and QFX Series switches.`

`server-reject-vlan` introduced in Junos OS Release 9.3 for EX Series.

`block-interval` introduced in Junos OS Release 11.2 for EX Series.

`server-reject-vlan` introduced in Junos OS Release 14.2 for MX240, MX480, and MX960 routers in enhanced LAN mode.

[edit tenants name security utm feature-profile anti-virus sophos-engine]
```

Description

Enable you to configure the server parameters for the device-to-server communication.

Starting in Junos OS Release 23.1R1, The Content Security supports the new antivirus Sophos Live Protection version 2.0. The new version of Sophos antivirus uses an HTTPS connection for the device-to-server communication. For the HTTPS connection, you must create an SSL initiation profile and add the profile to the default configuration of the Sophos engine. See profile (SSL Initiation) to create an SSL initiation profile.

Options

host

Specify the server host IP address or string host name.

- **Default:** 4.sophosxl.net

port

Specify the server port number.

- **Range:** 1 through 65535

- **Default:** 443

proxy-profile	Specify the proxy profile name.
`routing-instance` *name*	Specify the name of the routing instance.
source-address	Specify the source IP address used to connect Sophos server.
ssl-profile	Specify the SSL initiation profile name.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 15.1X49-D90.

The `[edit security utm default-configuration]` hierarchy level is introduced in Junos OS Release 18.2R1.

The `host`, `port`, and `ssl-profile` options introduced in Junos OS Release 23.1R1.

The `ip` option is deprecated in Junos OS Release 23.1R1.

The `proxy-profile` option introduced in Junos OS Release 24.4R1.

Release Information

The surf-control feature is not supported from Junos OS Release 15.1X49-D10 onwards. For previous releases, statement introduced in Junos OS Release 9.5 .

Statement introduced in Junos OS Release 11.4 .

The `[edit security utm default-configuration]` hierarchy level is introduced in Junos OS Release 18.2R1.

Change History Table

Feature support is determined by the platform and release you are using. Use Feature Explorer to determine if a feature is supported on your platform.

Release	Description
15.1X49-D10	The surf-control feature is not supported from Junos OS Release 15.1X49-D10 onwards.

server (TACACS+ Accounting)

IN THIS SECTION

- Syntax | 16674
- Hierarchy Level | 16675
- Description | 16675
- Options | 16675
- Required Privilege Level | 16676
- Release Information | 16676

Syntax

```
server {
    server-address {
        port port-number;
        routing-instance routing-instance;
        secret password;
        single-connection;
```

```
        source-address address
        timeout seconds;
    }
}
```

Hierarchy Level

```
[edit system accounting destination tacplus]
```

Description

Configure TACACS+ logging.

Options

server-address

Address of the IPv4 or IPv6 TACACS+ authentication server.

> **NOTE**: Wildcard characters cannot be used in the TACACS+ server address or source address. This is because the TACACS+ server and source can accept both IPv4 and IPv6 addresses and, if you use wildcard characters for these addresses, Junos OS cannot validate mismatching server and source address families.

port *port-number*

Configure the port number on which to contact the TACACS+ authentication server.

- **Default:** 49

routing-instance *routing-instance*

Configure the routing instance name for the management routing instance, that is `mgmt_junos`. Configuring this parameter along with the `management-instance` statement enables authentication processes (for example, RADIUS and TACACS+) to use the non-default management routing instance for packet traffic.

> **NOTE**: You must also define the mgmt_junos routing instance under the `[edit routing-instances]` hierarchy level.

If you no not configure the mgmt_junos instance under the `[edit routing-instances]` hierarchy level and configure it only under `tacplus-server` or `radius-server`, the commit will fail.

secret *password*

Configure the password to use with the RADIUS or TACACS+ server. The secret password used by the local router or switch must match that used by the server. The password can include spaces included in quotation marks.

> **NOTE**: To ensure better security, we recommend you configure the TACACS+ secret password with a minimum of 14 characters.

single-connection

Optimize attempts to connect to a TACACS+ server. The software maintains one open TCP connection to the server for multiple requests rather than opening a connection for each connection attempt.

source-address *source-address*

Specify a source address for each configured TACACS+ server to record in system log messages that are directed to a remote machine. Configure a valid IP address on one of the device interfaces. For system logging, the address is recorded as the message source in messages sent to the remote machines specified in all `host` *`hostname`* statements at the `[edit system syslog]` hierarchy level.

- **Default:** The primary address of the interface.

timeout *seconds*

The amount of time that the local device waits to receive a response from a TACACS+ server.

- **Default:** 3 seconds
- **Range:** 1 through 90 seconds

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

`routing-instance` option introduced in Junos OS Release 17.4R1.

service-context-id (OCS)

IN THIS SECTION

- Syntax | 16684
- Hierarchy Level | 16684
- Description | 16684
- Options | 16685
- Required Privilege Level | 16685
- Release Information | 16685

Syntax

```
service-context-id service-context ;
```

Hierarchy Level

```
[edit access ocs global]
```

Description

Configure the service-context-id to globally and uniquely identify the Service-Context-Id AVP (cc-service-context) and the Service-Identifier AVP (cc-service-identifier), which is part of the Diameter Credit Control Service charging system. The service provider or operator allocates this identifier.

Options

service-context

3rd Generation Partnership Project (3GPP)-specific values.

- *service-context*—32251
- *customer-domain*—3gpp.org

> **NOTE**: For every service used to support the packet-switching charging infrastructure, you must prepare the necessary documentation and define associated cc-service-context-id values.

For mobile subscribers, the user equipment requests services; whereas for broadband wireline subscribers, the Policy Control and Charging Rules Function (PCRF) requests services. In the wireline environment, PCRF functions as the service requester, and the Policy and Charging Enforcement Function (PCEF) functions as the service receiver and enforcer.

The PCRF controls the PCEF by pushing charging rules. Charging rules are reused as service (policy) rules to push policies. Charging rules may also have an associated rating group, or charging key. As a result, you must configure the PCEF to define a charging rules mapping between credit control services (cc-services) and rating groups.

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 16.2.

service-device (Remote Device Management)

IN THIS SECTION

- Syntax | 16690
- Hierarchy Level | 16691
- Description | 16691
- Options | 16691
- Required Privilege Level | 16692
- Release Information | 16692

Syntax

```
service-device device-name {
    access-domain {
        vlan-id-list [vlan-id-low-vlan-id-high vlan-id]
    }
    address ip-address;
    dictionary absolute file path;
    provisioning-method {
        netconf {
            bulk-interval milliseconds;
            bulk-limit number;
            connection-retry-interval seconds;
            password password;
            port port-number;
            reconfigure-bulk-limit number;
            response-timeout seconds;
            response-timeout-count number;
            user-name name;
        }
```

```
    }
}
```

Hierarchy Level

```
[edit routing-instances routing-instance-name system services remote-device-management],
[edit system services remote-device-management]
```

Description

Configure a remote device to provision and deprovision services for subscribers. This configuration is used when `profile-type remote-device-service` has been configured in the dynamic service profile.

Provides basic configuration for the remote service device and enables NETCONF TCP session to be established with the service-device. Subsequently, dynamic configuration of the access-domain occurs based on allocation and assignment of individual VLAN IDs or VLAN ranges for one or more subscriber sessions.

> **NOTE**: With the exception of the `access-domain` statement, all statements are required to be configured for the service device and are subject to a commit check. This behavior enables basic configuration for the remote device and the NETCONF TCP session to be completed followed later by dynamic configuration of the access-domain based on allocation and assignment of individual VLAN IDs or VLAN ranges for one or more subscriber sessions.

Options

address *ip-address*

Specify the IP address of the remote device used by the BNG to configure the subscriber service. The address must be unique; it is used for all actions performed by the BNG, including service provisioning and deprovisioning. The address must also be unique across all routing instances.

> **NOTE**: You cannot change the IP address for the device when any active subscriber services are mapped to it.

device-name

System-wide name that uniquely identifies the device across routing instances.

dictionary *absolute file path*

Specify the absolute file path for the vendor-specific dictionary that defines the set of NETCONF XML protocol commands required to provision, deprovision, and roll back a subscriber service on the remote device. The dictionary is stored on the BNG. An example absolute path is **/var/home/dict/remote-device.xml**.

Because the dictionary is assigned to a service device, you can use service devices from different vendors at the same time. This assignment method also enables you to use multiple devices from the same vendor that are running different software releases. This is useful because the NETCONF XML protocol commands to configure the devices can differ across releases.

> **NOTE**: The maximum total length of the path is 127 characters. The filename must end in `xml`.

> **NOTE**: You cannot change the dictionary path for the device when any active subscriber services are mapped to it.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

system—To view this statement in the configuration.

Release Information

Statement introduced in Junos OS Release 18.3R1.

service input service-set service-set-name],
[edit dynamic-profiles profile-name interfaces pp0 unit "$junos-interface-unit" family family
service output service-set service-set-name]
```

Description

Define the filter to be applied to traffic before it is accepted for service processing. You can use the predefined dynamic interface variables `$junos-input-service-filter`, `$junos-output-service-filter`, `$junos-input-ipv6-service-filter`, and `$junos-output-ipv6-service-filter`. Configuration of a service filter is optional; if you include the `service-set` statement without a `service-filter` definition, the router software assumes that the match condition is true and selects the service set for processing automatically.

Options

`filter-name`—Identifies the filter to be applied in service processing.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.5.

Support at the [`edit dynamic-profiles` *`profile-name`* `interfaces pp0 unit "$junos-interface-unit" family` *`family`* `service input service-set` *`service-set-name`*] and [`edit dynamic-profiles` *`profile-name`* `interfaces pp0 unit "$junos-interface-unit" family` *`family`* `service output service-set` *`service-set-name`*] hierarchy levels introduced in Junos OS Release 10.1.

service-filter (Firewall)

IN THIS SECTION

- Syntax | **16699**
- Hierarchy Level | **16700**
- Description | **16700**
- Options | **16700**
- Required Privilege Level | **16700**
- Release Information | **16700**

Syntax

```
service-filter filter-name {
    term term-name {
        from {
            match-conditions;
        }
        then {
            actions;
        }
    }
}
```

Hierarchy Level

```
[edit firewall family (inet | inet6],
[edit logical-systems logical-system-name firewall family (inet | inet6)]
```

Description

Configure service filters.

NOTE: ACX Series routers do not support `family` *`inet6`*.

Options

filter-name—Name that identifies the service filter. The name can contain letters, numbers, and hyphens (-) and can be up to 255 characters long. To include spaces in the name, enclose it in quotation marks (“ ”).

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

firewall—To view this statement in the configuration.

firewall-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Logical systems support introduced in Junos OS Release 9.3.

- Hierarchy Level | 16703
- Description | 16703
- Options | 16703
- Required Privilege Level | 16703
- Release Information | 16703

Syntax

```
service-groups {
    service-group-name {
        pbb-service-options {
            default-isid isid-number;
            isid isid-number  vlan-id-list [ vlan-ids ];
            mac-address mac-address;
```

```
        }
        service-type  (elan | eline);
        source-bmac <mac-address> <length>
    }
}
```

Hierarchy Level

```
[edit routing-instances (Multiple Routing Entities) routing-instance-name]
```

Description

For IEEE 802.1ah provider backbone bridge (PBB) configurations, configure the service groups to be supported in the customer routing instance (I-component).

NOTE: The `mac-address` statement under `pbb-service-options` is not supported for PBB-EVPN.

NOTE: The `eline` option for the `service-type` statement is not supported for PBB-EVPN.

The remaining statements are explained separately. See CLI Explorer.

Options

service-group-name—Name of a service group.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in JUNOS Release 10.0.

service-id (Bridge Domains)

IN THIS SECTION

- Syntax | 16704
- Hierarchy Level | 16704
- Description | 16704
- Options | 16704
- Required Privilege Level | 16705
- Release Information | 16705

Syntax

```
service-id number;
```

Hierarchy Level

```
[edit bridge-domains bridge-domain-name]
```

Description

Specify a service identifier to include in the packets sent to and from the multichassis link aggregation (MC-LAG) bridge domain when the VLAN identifier is set to `none`. This configuration facilitates media access control (MAC) and Address Resolution Protocol (ARP) synchronization among MC-LAG peers.

NOTE: The VLAN identifier none is supported only for IPv4 traffic.

Options

number—A valid service identifier. You must configure the same service identifier within the bridge domains of MC-LAG peers.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 13.2

- Required Privilege Level | 16707

Release Information | 16708

Syntax

```
service-interface interface-name;
```

Hierarchy Level

```
[edit services l2tp tunnel-group name]
```

Description

Specify the service interface responsible for handling L2TP processing.

NOTE: On MX Series routers, the service interface configuration is required for static LNS sessions. Either the service interface configuration or the service device pool configuration can be used for dynamic LNS sessions.

Options

interface-name Name of the service interface. The ae, si, and sp interface types are supported as follows:

- `asix`—(MPCs on MX Series routers) Aggregated inline services interface.
- `sp-fpc/pic/port`—On AS or Multiservices PICs on M7i, M10i, and M120 routers.
- `si-fpc/pic/port`—On MPCs on MX Series routers.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

`si-fpc/pic/port` option added in Junos OS Release 11.4.

Option `asifpc` added in Junos OS Release 16.2.

service-mode

IN THIS SECTION

- Syntax | 16711
- Hierarchy Level | 16711
- Description | 16711
- Options | 16712
- Required Privilege Level | 16712
- Release Information | 16712

Syntax

```
service-mode service-mode-options;
```

Hierarchy Level

```
[edit routing-instances vrf-name access address-assignment address-pools juniper-pool],
[edit unified-edge gateways tdf gateway-name],
[edit unified-edge gateways tdf gateway-name domains domain-name],
[edit unified-edge tdf gateway-name system interface interface-name],
[edit unified-edge gateways tdf gateway-name system session-pics interface interface-name]
```

Description

Set maintenance mode for a network element so that you can carry out maintenance tasks such as deleting or modifying the element, for example, an address pool.

When in the maintenance mode active phase, you can modify all the valid attributes on the network element. In other cases, you can modify only the non-maintenance mode attributes.

The following network elements must be in maintenance mode before you can modify or delete them:

- Address pools
- AMS interfaces
- PCEF profiles
- Session PICs
- Service PICs
- Static time-of-day settings
- TDF domains
- TDF interfaces
- TDF gateways

Options

service-mode-options Type of the service mode. Currently, only **maintenance** mode is supported.

Required Privilege Level

unified-edge—To view this statement in the configuration.

unified-edge-control—To add this statement to the configuration.

Maintenance Mode Overview for Subscriber Aware Policy Enforcement

service-mode (mobile-edge SAEGW)

IN THIS SECTION

- Syntax | 16713
- Hierarchy Level | 16713
- Description | 16713
- Required Privilege Level | 16714
- Release Information | 16714

Syntax

```
service-mode {
      maintenance
      }
}
```

Hierarchy Level

```
[edit services mobile-edge gateways saegw gateway-name system]
```

Description

Enter maintenance mode for SAEGW gateways. This makes your gateway inactive for new sessions, but traffic flow and existing sessions will continue uninterrupted. Critical session modify and session delete messages are also allowed in maintenance mode.

When you enter maintenance mode, a duration is set for the maintenance window. The maintenance window can be ended early with a new load control information (LCI) message. If maintenance mode is entered in response to an overload control information (OCI) message, the maintenance window must run for the specified duration in the OCI message.

If the load/overload feature is not enabled, a warning message will be displayed and the command will be rejected.

To enter maintenance mode, enter the following command:

```
user@host# set services mobile-edge gateways saegw gateway-name system service-mode maintenance
```

To leave maintenance mode, enter this command:

```
user@host# delete services mobile-edge gateways saegw gateway-name system service-mode
maintenance
```

To end maintenance mode, use the `delete` command instead of the `set` command.

Required Privilege Level

system

Release Information

Juniper Networks released this statement in Junos OS Release 23.1R1.

service-name

IN THIS SECTION

- Syntax | 16715
- Hierarchy Level | 16715
- Description | 16715

    reverse-flow [ service-name1 service-name2 ];
}
```

Hierarchy Level

```
[edit services service-set service-set-name]
```

Description

Define the order of services in service set to be applied to traffic coming to the PIC.

NOTE: If the `extension-service` statement is specified, the `service-order` statement is mandatory.

Options

`forward-flow`—Order of services in service set to be applied in forward flow.

`reverse-flow`—Order of services in service set to be applied in reverse flow. If you want the order to be the reverse of that specified for forward flow, this is optional. However, if, for example, you want the order to be the same regardless of direction of flow, you must include this statement. (The exception to this is for the sampling service set type. If a service set is a sampling service set and the reverse-flow service order is not configured, all sampled traffic is considered to be forward traffic.)

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

        }
    }
}
```

Hierarchy Level

```
[edit protocols pppoe service-name-tables table-name]
```

Description

Specify the action taken by the interface on receipt of a PPPoE Active Discovery Initiation (PADI) control packet for the specified named service, `empty` service, or `any` service in a PPPoE service name table. You can also specify the dynamic profile and routing instance that the router uses to instantiate a dynamic PPPoE interface, and the maximum number of active PPPoE sessions that the router can establish with the specified service.

Default

The default action is terminate.

Options

service-name—Service entry in the PPPoE service name table:

- *service-name*—Named service entry of up to 32 characters; for example, `premiumService`. You can configure a maximum of 512 named service entries across all PPPoE service name tables on the router.
- `empty`—Service entry of zero length that represents an unspecified service. Each PPPoE service name table includes one `empty` service entry by default.
- `any`—Default service for non-empty service entries that do not match the named or `empty` service entries configured in the PPPoE service name table. Each PPPoE service name table includes one `any` service entry by default.

[edit logical-systems logical-system-name routing-instances routing-instance-name system
services dhcp-local-server ...],
[edit routing-instances routing-instance-name system services dhcp-local-server ...]
```

Description

Specify the default subscriber service or DHCP client management service, which is activated when the subscriber or client logs in and no other service is activated by a RADIUS server or a provisioning server.

- To specify the default service for all DHCP local server clients, include the `service-profile` statement at the `[edit system services dhcp-local-server]` hierarchy level.
- To specify the default service for a named group of interfaces, include the `service-profile` statement at the `[edit system services dhcp-local-server group group-name]` hierarchy level.
- To specify the default service for a particular interface within a named group of interfaces, include the `service-profile` statement at the `[edit system services dhcp-local-server group group-name interface interface-name]` hierarchy level.
- For DHCPv6 clients, use the `service-profile` statement at the `[edit system services dhcp-local-server dhcpv6]` hierarchy level.

Options

dynamic-profile-name—Name of the dynamic profile that defines the service.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.2.

Default Subscriber Service Overview

service-profile (L2TP)

IN THIS SECTION

- Syntax | 16733
- Hierarchy Level | 16733
- Description | 16733
- Options | 16734
- Required Privilege Level | 16734
- Release Information | 16734

Syntax

```
service-profile profile-name(parameter)&profile-name;
```

Hierarchy Level

```
[edit access profile profile-name client client-name l2tp]
[edit services l2tp tunnel-group group-name]
```

Description

Configure one or more dynamic service profiles to be applied to subscriber sessions at activation for all subscribers in the specified tunnel group or on the specified LAC. Services are typically applied to L2TP sessions with RADIUS VSAs or CoA requests. In multivendor environments, you might use only standard

attributes to simplify management of multiple vendor VSAs. This statement enables you to apply services without using an external authority such as RADIUS. The locally configured list of services (service profiles) serves as local authorization that is applied by authd during client session activation. This list of services is subject to the same validation and processing as services originating from an external authority, such as RADIUS.

You can optionally specify parameters that are passed to the corresponding service when it is activated for the session. The parameter might override values configured in the profile itself, such as a downstream shaping rate for a CoS service. This enables you to use the same service profile for multiple situations with different requirements, or to modify a previously applied value for a service.

You can still use RADIUS VSAs or CoA requests together with the service profiles. If services are sourced from an external authority as authorization during authentication or during subscriber session provisioning (activation), the services from the external authority take strict priority over those in the local configuration. If a service applied with RADIUS is the same as a service applied with a service profile in the CLI, but with different parameters, the RADIUS service is applied with a new session ID and takes precedence over the earlier service profile.

When service profiles are configured on a LAC client and on a tunnel group that uses that LAC client, the LAC configuration overrides the tunnel group configuration. Only the service profile configured on the LAC client is applied to subscribers in the tunnel group.

Options

profile-name Name of a dynamic service profile that defines a service to be applied to L2TP subscriber sessions. You can specify one or more service profiles, separated by an ampersand (&).

parameter (Optional) Value to be passed to the service when it is activated on the subscriber session.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 18.1R1 on MX Series routers.

service-profile (Static Subscribers)

IN THIS SECTION

- Syntax | 16735
- Hierarchy Level | 16735
- Description | 16735
- Options | 16736
- Required Privilege Level | 16736
- Release Information | 16736

Syntax

```
service-profile service-profile-name;
```

Hierarchy Level

```
[edit system services static-subscribers],
[edit system services static-subscribers group group-name]
```

Description

Specify the service profile to apply services for all static subscribers at the global level and at the group level. You can use `service-profile` to assign a default service profile to be applied to a `static-subscriber` session if the policy server is unavailable.

Options

service-profile-name—Name of the service profile.

Required Privilege Level

access—To view this statement in the configuration.

access-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 17.4R1.

service-set (Application-Aware Control Policy)

IN THIS SECTION

- Syntax | 16740
- Hierarchy Level | 16741
- Description | 16741
- Options | 16741
- Required Privilege Level | 16742
- Release Information | 16742

Syntax

```
service-set service-set-name {
    application-identification-profile app-id-profile-name;
    interface-service {
```

```
        service-interface interface-name;
    }
    hcm-profile profile-name;
    lrf-profile profile-name;
    pcef-profile pcef-profile-name;
    service-set-options {
        subscriber-awareness;
        static-subscriber-application;
    }
}
```

Hierarchy Level

```
[edit services]
```

Description

Configure a service set to identify the service interface that handles application-aware policy control.

Options

application-identification–profile *app-id-profile-name*

Specify a dummy application identification profile that you configured at the `[edit services application-identification profile]` hierarchy level. This profile is a placeholder profile with no configuration options, but it must be specified to enable application identification functionality on the services plane.

hcm-profile *profile-name*

Identify the HTTP Content Manager profile that was configured at the `[edit services hcm]` hierarchy level. This placeholder profile has no configuration options, but it must be specified to enable HTTP header enrichment functionality on the services plane.

lrf-profile *profile-name*

Identify the LRF profile that defines the logging of subscriber application-aware data sessions. The LRF profile must first be configured at the `[edit services lrf]` hiearchy level.

pcef-profile *pcef-profile-name*

Specify a dummy PCEF profile that you configured at the `[edit services pcef]` hierarchy level. This profile is a placeholder profile with no configuration options, but it must be specified to enable application-aware policy control functionality on the services plane.

service-interface ***interface-name***	Specify the services PIC interface on which the services are performed.
service-set-name	Name of the service set.
static-subscriber-application	Apply advanced services, such as deep packet inspection, to static subscribers configured under a dynamic profile.
subscriber-awareness	Enable subscriber-aware services on the service set.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement options for application-aware policy control introduced in Junos OS Release 17.2R1 on MX Series for Broadband Subscriber Management.

USF support for statement options for application-aware policy control introduced in Junos OS Release 19.3R2 on MX Series for Broadband Subscriber Management.

`static-subscriber-application` option added in Junos OS Release 21.2R1.

service-set (Dynamic Service Sets)

IN THIS SECTION

- Syntax | **16743**
- Hierarchy Level | **16743**

- Description | 16743
- Options | 16744
- Required Privilege Level | 16744
- Release Information | 16744

Syntax

```
service-set service-set-name {
    service-filter filter-name;
}
```

Hierarchy Level

```
[edit dynamic-profiles profile-name interfaces interface-name unit logical-unit-number family
family service input],
[edit dynamic-profiles profile-name interfaces interface-name unit logical-unit-number family
family service output],
[edit dynamic-profiles profile-name interfaces pp0 unit “$junos-interface-unit” family family
service input],
[edit dynamic-profiles profile-name interfaces pp0 unit  “$junos-interface-unit” family family
service output]
```

Description

Define one or more service sets in a dynamic profile. Service sets are applied to an interface. If you define multiple service sets, the router software evaluates the filters in the order in which they appear in the configuration. You can use the predefined dynamic interface variables `$junos-input-service-set`, `$junos-output-service-set`, `$junos-input-ipv6-service-set`, and `$junos-output-ipv6-service-set`.

NOTE: Starting in Junos OS Release 17.2R1, you can configure converged services at the `edit dynamic-profiles http-redirect-converged` hierarchy level. CPCD rules can also be configured under the dynamic profiles stanza to achieve parameterization of the rules.

This mechanism provides additional flexibility to customize the different rules on a per subscriber basis through service attachment.

Options

service-set-name—Name of the service set.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.5.

Support at the `[edit dynamic-profiles profile-name interfaces pp0 unit "$junos-interface-unit" family family service input]` and `[edit dynamic-profiles profile-name interfaces pp0 unit "$junos-interface-unit" family family service output]` hierarchy levels introduced in Junos OS Release 10.1.

From 17.2R1 onwards, you can configure converged services at the `edit dynamic-profiles http-redirect-converged` hierarchy level.

`ptsp-rules` and `ptsp-rule-sets` options added in Junos OS Release 10.2.

`softwire-rules` and `clear-rule-sets` options added in Junos OS Release 10.4.

`ip-reassembly-rules` and `outside-service-interface-type` option added in Junos OS Release 13.1R1.

`pcp-rules` option added in Junos OS Release 13.2R1.

`softwire-options` option added in Junos OS Release 14.1.

`subscriber-awareness` option added in Junos OS Release 17.1R1.

`url-filter-profile` option added in Junos OS Release 17.2R1.

`match-rules-on-reverse-flow` option added in Junos OS Release 16.1R5 and 17.4R1.

`no-certificate-chain-in-ike` option added in Junos OS Release 18.2R1.

`web-filter-profile` option added in Junos OS Release 18.3R1, replacing the deprecated `url-filter-profile` option.

`max-session-setup-rate` option added in Junos OS Release 19.1R1, replacing the deprecated option `max-session-creation rate`, which was added in Junos OS Release 17.1R1.

Support added in Junos 20.2R1 for Next Gen Services NAT PT feature.

`static-subscriber-application` option added in Junos OS Release 21.2R1.

service-tracking-action (Network Isolation Groups)

IN THIS SECTION

- Syntax | 16758
- Hierarchy Level | 16758
- Description | 16758
- Options | 16759
- Required Privilege Level | 16759
- Release Information | 16759

Syntax

```
service-tracking-action (lacp-out-of-sync | link-down);
```

Hierarchy Level

```
[edit protocols network-isolation group name]
```

Description

Set the action the device takes for the interface or interfaces associated with a configured network isolation group profile, when the device detects a network isolation condition change.

A network isolation group encompasses the parameters that the device uses to:

- Detect when an EVPN instance. a bridge domain, or a VLAN is in a network isolation state.
- Take actions on the associated interfaces after the device detects a network isolation status change.

You set this option as part of configuring parameters that define a network isolation group for network isolation service tracking. When you configure this option in a network isolation group, you also must:

- Enable service tracking in the network isolation group to detect network isolation condition changes.

To do this, include the "service-tracking" on page 16760 statement at the `[edit protocols network-isolation group group-name detection]` hierarchy. With the `service-tracking` statement, you set a supported network isolation condition to track (such as `core-isolation`).

- Assign the network isolation group to an interface where you want the device to perform the action when the configured network isolation condition happens.

  To do this, set the network isolation group name for the desired interface or interfaces using the `network-isolation-profile group group-name` statement at the `[edit interfaces interface-name]` hierarchy.

Options

Actions the device can perform on the interfaces associated with the network isolation group upon detecting the configured network isolation condition:

lacp-out-of-sync Set LACP out of sync state for the associated ESI LAG interfaces.

link-down Bring down the interface or interfaces.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS and Junos OS Evolved Release 23.2R1.

Layer 2 Interface Status Tracking and Shutdown Actions for EVPN Core Isolation Conditions

service-tracking (Network Isolation Groups)

IN THIS SECTION

- Syntax | 16760
- Hierarchy Level | 16760
- Description | 16760
- Options | 16761
- Required Privilege Level | 16761
- Release Information | 16761

Syntax

```
service-tracking {
    core-isolation;
}
```

Hierarchy Level

```
[edit protocols network-isolation group name detection]
```

Description

Enable service tracking in a network isolation group to detect core isolation condition changes.

When you set this option, you must also do the following:

- In the same network isolation group definition, configure the actions the device should take upon detecting a core isolation condition.

  To do this, configure the `service-tracking-action` statement at the `[edit protocols network-isolation group name detection]` hierarchy.

- Assign the network isolation group to the interface or interfaces on which the device should take action upon detecting a core isolation condition.

To do this, configure the `network-isolation-profile group group-name` statement at the `[edit interfaces interface-name]` hierarchy.

The interface to which you assign these parameters can be:

- A logical single link or aggregated Ethernet (AE) link bundle (LAG) to a single-homed customer edge device in the network.
- An Ethernet segment identifier (ESI) LAG interface to a multihomed customer edge device in the network.
- A physical interface.

Options

core-isolation Enable service tracking for EVPN core isolation conditions.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS and Junos OS Evolved Release 23.2R1.

Syntax | **16762**

- Hierarchy Level | 16762
- Description | 16762
- Options | 16762
- Required Privilege Level | 16762
- Release Information | 16763

Syntax

```
service-type (elan | eline);
```

Hierarchy Level

```
[edit routing-instances (Multiple Routing Entities) routing-instance-name service-groups]
```

Description

For IEEE 802.1ah provider backbone bridge (PBB) configurations, configure the service type for the service group in the customer routing instance (I-component).

Options

`elan`—Connects a set of customer endpoints (like a bridged Ethernet network). E-LAN service is also known as point-to-multipoint service.

`eline`—Connects two customer Ethernet ports over a WAN. E-LINE service is also known as point-to-point service.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in JUNOS Release 10.0.

service-type (RFC 2544 Benchmarking Tests)

IN THIS SECTION

- Syntax | 16763
- Hierarchy Level | 16763
- Description | 16763
- Options | 16764
- Required Privilege Level | 16764
- Release Information | 16764

Syntax

```
service-type (elan | eline) ;
```

Hierarchy Level

```
[edit services rpm rfc2544-benchmarkingtests test-name test-name]
```

Description

Configure the service under test. Possible values are `elan` and `eline`. This statement is applicable only for the `bridge` family, the `ethernet-switching` family, or when the `mode` is configured as reflect. When the service type is `elan`, MAC addresses are swapped by default on the reflected frames. The `no-mac-swap` option is not supported for this service type. When the service type is `eline`, MAC addresses are not swapped by default in the reflected frames. Use the `mac-swap` option to swap the addresses.

> **NOTE**: When you configure Layer 2 reflection, you can specify the service type under test as `eline` if you want to simulate an E-Line service using bridge encapsulation.

Options

elan Specify the ELAN service type.

eline Specify the E-Line service type.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.3X53.

Statement introduced in Junos OS Evolved Release 22.4R1.

service-type (MAC-VRF Routing Instances)

IN THIS SECTION

Syntax | **16765**

- Hierarchy Level | 16765
- Description | 16765
- Options | 16765
- Required Privilege Level | 16766
- Release Information | 16766

Syntax

```
service-type (vlan-aware | vlan-based | vlan-bundle);
```

Hierarchy Level

```
[edit logical-systems name routing-instances mac-vrf routing-instance name],
[edit logical-systems name tenants name routing-instances mac-vrf routing-instance name],
[edit routing-instances mac-vrf routing-instance name],
[edit tenants name routing-instances mac-vrf routing-instance name]
```

Description

Select the type of VLAN service that the MAC-VRF routing instance provides. The selected option controls how the routing instance maps VLANs to the forwarding instances on the device.

Options

vlan-aware Map one or more routing instances of type Virtual Switch to many VLAN IDs (VIDs) and multiple bridge tables. Each bridge table corresponds to a different VLAN.

vlan-based Map one routing instance of type EVPN to one VLAN. Only one bridge table corresponds to one VLAN. If the VLAN consists of multiple VLAN IDs (VIDs), then you must configure VLAN translation for packets that are traveling to the Ethernet segment. You do this when you use a different VID per Ethernet segment on a provider edge device.

vlan-bundle Map multiple broadcast domains to a single bridge domain. Multiple VLANs map to a single EVPN instance (EVI) and share the same bridge table in the MAC-VRF table. This configuration reduces the number of routes and labels stored in the table.

CAUTION: When you want to change a traffic impacting option under a routing instance, use the following procedure.

1. Deactivate the routing instance configuration.
2. Change the traffic impacting option.
3. Reactivate the updated routing instance configuration.

For example, follow this procedure if you need to change settings such as:

- The `service-type` in a MAC-VRF routing instance—When you change the service type of a running instance, the device might incorrectly change the VLAN ID if it is not deactivated prior to making the change.
- The `vlan-id` in an EVPN routing instance—Changing the `vlan-id` on the fly, without first deactivating the associated EVPN routing instance would be catastrophic.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 20.4R1.

Syntax

```
service-provider service-provider {
    assertion-waittime assertion-waittime;
    encrypted-assertions;
    entity-id entity-id;
    hash-algorithm <sha-256 | sha-384 | sha-512>;
    sign-auth-request;
    sp-certificate sp-certificate;
}
```

Hierarchy Level

```
[edit access saml]
```

Description

Describe Security Assertion Markup Language (SAML) service provider configuration details.

Options

assertion-waittime ***assertion-waittime***	Set the maximum waiting time for an assertion from the Identity Provider (IdP). • Value: Within a range of 1 to 600 seconds • Default: 30 seconds
encrypted-assertions	Specify that the IdP must provide encrypted assertions.
entity-id ***entity-id***	Specify service provider entity ID.
hash-algorithm <sha-256 | sha-384 | sha-512>	Define the signature hash algorithm. • Value: Supports sha-256, sha-384, or sha-512 • Default: sha-256
sign-auth-request	Sign the SAML authentication request.
sp-certificate ***sp-certificate***	Specify the service provider certificate.

Required Privilege Level

access—To view this statement in the configuration.

access-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 24.4R1.

                destination-port destination-port;
            }
        }
        rule rule-name {
            match-direction (input | output | input-output);
            from {
                destination-address address <except>;
            }
            term term-name {
                then {
                    accept;
                    insert tag tag-name tag-value tag-value;
                    redirect url;
```

```
                    rewrite destination-address address <destination-port port-number>;
                    syslog;
                }
            }
        }
        rule-set rule-set-name {
            [rule rule-name];
        }
        traceoptions {
            file <filename> <files files> <match match> <size size> <(world-readable | no-world-
readable)>;
            flag name;
            no-remote-trace no-remote-trace;
        }
    }
}
```

Hierarchy Level

```
[edit],
[edit dynamic-profiles profile-name]
```

Description

Define the captive portal content delivery set of the rules statements to be applied to traffic. Use the statement at the `[edit services...]` hierarchy level for static CPCD. Use the statement at the `[edit dynamic-profiles profile-name services...]` hierarchy level for converged services CPCD.

The `profile`, `rule-set`, and `traceoptions` stanzas are not supported at the `[edit dynamic-profiles profile-name hierarchy level]`.

Configure the HTTP redirect service by specifying the location to which a subscriber's initial Web browser session is redirected, enabling initial provisioning and service selection for the subscriber. Use the statement at the `[edit services...]` hierarchy level for static CPCD. Use the statement at the `[edit dynamic-profiles profile-name services...]` hierarchy level for converged services CPCD.

The `profile`, `rule-set`, and `traceoptions` stanzas are not supported at the `[edit dynamic-profiles profile-name hierarchy level]`.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Options

auto-deactivate *value*

(Optional) Specify one of the following values to determine whether the redirect service is removed automatically when the router receives the subscriber's initial HTTP-GET message:

- *user-defined-variable*—To use this option in a dynamic profile, you must create a user-defined variable with a name of your choice. The value of the variable can be supplied by the RADIUS server or PCRF. You can also define a default value that is used when the external servers do not supply it. Use the "variables" on page 30654 statement in the dynamic profile to define the default value. Whether supplied by the external server or by the CLI, the value must be either `initial-get` or `never`.
- `initial-get`—Receipt of the subscriber's initial HTTP-GET message triggers removal of the redirect service.
- `never`—Removal of the redirect service is triggered only by the external server, such as by a CoA message from a RADIUS server.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level

services—To view this statement in the configuration.

services–control—To add this statement to the configuration.

services-memory (resource-manager)

IN THIS SECTION

- Syntax | 16782
- Hierarchy Level | 16782
- Description | 16782
- Options | 16782
- Required Privilege Level | 16783
- Release Information | 16783

Syntax

```
services-memory {
    match {
        threshold threshold;
    }
    then {
        alarm;
        drop-flows;
        fail-close;
        fail-open;
        log;
    }
}
```

Hierarchy Level

```
[edit security resource-manager]
```

Description

Configure resource manager services-memory options to control the behavior of the device based on memory load.

Options

- `threshold` *`threshold`*-Configure the threshold limit to let `resource-manager` take actions when the service memory load exceeds the threshold. The range is 1 to 100 percent.
- `fail-close`-This configuration closes a session when there is not enough memory for a service during session setup. This configuration drops a packet if there is not memory during fast path. This is the default configuration.
- `fail-open`-This configuration opens a infra session even if there is not enough memory for a service to allocate memory.
- `drop-flows`-When you mark a session as a drop-flow, it bypasses the first path for each new packet, which matches the original drop session for next 4 seconds only. This configuration drops the packets that match the `drop-flows`.

- `log`-This configuration logs messages when the resource threshold is exceeded and falls back under the threshold, and what is the protective action taken.
- `alarm`-This configuration sends an SNMP trap when the memory load exceeds the threshold.

Required Privilege Level

security—To view this in the configuration.

security-control—To add this to the configuration.

Release Information

Statement introduced in Junos OS Release 20.4R1.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

services-offload

IN THIS SECTION

- Syntax | 16785
- Hierarchy Level | 16785
- Description | 16785
- Options | 16785
- Required Privilege Level | 16785
- Release Information | 16785

Syntax

```
services-offload {
    low-latency;
    per-session-statistics;
}
```

Hierarchy Level

```
[edit chassis fpc fpc-slot-number pic pic-slot-number]
```

Description

Enables the Express Path mode (formerly known as *services offloading*) mode on the selected network processor. Services-offload is not enabled by default.

When services-offload is enabled, only the first packets of a session goes to the Services Processing Unit (SPU), rest of packets in services-offload mode does not go to SPU, therefore some security features such as stateful screen are not supported. Only TCP and UDP packets can be services offloaded.

Options

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

security—To view this in the configuration.

security-control—To add this to the configuration.

Release Information

Statement introduced in Junos OS Release 11.4.

            trace-level (brief | detail | error);
        }
```

Hierarchy Level

```
[edit interfaces interfaces-name]
```

Description

Define the service options to be applied on the virtual multi-service (VMS) interface.

This statement is supported only on the MX-SPC3 Services Card.

The remaining statements are explained separately. See CLI Explorer.

Options

file Configure the trace file options.

filename Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory `/var/log`. By default, the name of the file is the name of the process being traced.

files *number* Maximum number of trace files. When a trace file named *`trace-file`* reaches its maximum size, it is renamed to *`trace-file`*`.0`, then *`trace-file`*`.1`, and so on, until the maximum number of trace files is reached. The oldest archived file is overwritten.

If you specify a maximum number of files, you also must specify a maximum file size with the `size` option and a filename.

- **Range:** 2 through 1000 files
- **Default:** 10 files

match *regular-expression*

Refine the output to include lines that contain the regular expression.

size *maximum-file-size*

Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named *trace-file* reaches this size, it is renamed *trace-file*.0. When the trace-file again reaches its maximum size, *trace-file*.0 is renamed *trace-file*.1 and *trace-file* is renamed *trace-file*.0. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you also must specify a maximum number of trace files with the files option and a filename.

Syntax: *x* K to specify KB, *x* m to specify MB, or *x* g to specify GB

- **Range:** 0 KB through 1 GB
- **Default:** 128 KB

world-readable | no-world-readable

By default, log files can be accessed only by the user who configures the tracing operation. The world-readable option enables any user to read the file. To explicitly set the default behavior, use the no-world-readable option.

flag

Trace operation to perform. To specify more than one trace operation, include multiple flag statements.

all

Trace with all flags enabled

basic-datapath

Trace basic packet flow activity

fragmentation

Trace IP fragmentation and reassembly events

high-availability

Trace flow high-availability information

host-traffic

Trace flow host traffic information

multicast

Trace multicast flow information

route

Trace route lookup information

session	Trace session creation and deletion events
session-scan	Trace session scan information
tcp-basic	Trace TCP packet flow information
tunnel	Trace tunnel information

no-remote-trace
Set remote tracing as disabled.

packet-filter *filter-name*
Packet filter to enable during the tracing operation. Configure the filtering options.

destination-port *port-identifier*	Match TCP/UDP destination port
destination-prefix *address*	Destination IP address prefix
interface *interface-name*	Logical interface
protocol *protocol-identifier*	Match IP protocol type
source-port *port-identifier*	Match TCP/UDP source port
source-prefix *address*	Source IP address prefix

rate-limit *messages-per-second*
Limit the incoming rate of trace messages.

trace-level
Set the level for trace logging. This option is available only when the flag is set.

brief	Trace key flow information, such as message types sent between SPU and central point, policy match, and packet drop reasons.
detail	Trace extensive flow information, such as detailed information about sessions and fragments. Detail is the default level.
error	Trace error information, such as system failure, unknown message type, and packet drop.

fragment-limit
Specify the maximum number of fragments to be supported for the PIC. This overrides the value specified, if any, in the `set security flow fragment-limit` statement.

reassembly-timeout
Specify the reassembly timeout value for all fragmentation packets for the PIC. This overrides the value specified, if any, in the `set security flow reassembly-timeout` statement

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 19.3R2.

Support introduced in Junos OS Release 20.3R1 for Next Gen Services on MX240, MX480 and MX960 routers for the `flow` configuration statement.

```

Hierarchy Level

```
[edit chassis high-availability]
```

Description

Configure a service redundancy group (SRG). An SRG includes and manages a collection of resources on both nodes of a Multinode High Availability and it fails over between the two devices. You can configure upto 20 SRGs in a Multinode Highavailability setup.

Options

name

Services redundancy group identifier.

- **Range:** 0 through 20

active-signal-route

IP address used for route preference advertisement. You must specify the active signal route along with the route-exists policy in the policy-options statement.

Signal route required for active role enforcement. When you configure the `active-signal-route` with `if-route-exists` condition, the HA module adds this route to the routing table.

- ip-address—IP address for active signal route
- routing-instance—Routing instance of the active signal route.

activeness-priority

Specify priority for the SRG1 in a node to take up the active role in a case where both nodes initialize at the same time. The node where SRG1 is in active state is considered as active node.

If you prefer a certain node to take over as the active node on boot, you can do one of the followings:

- Configure the upstream routers to include preferences for the path where the node is located.
- Configure the activeness priority for SRG1 on the SRX Series device (higher activeness priority). You can configure a priority for each node. As long as the nodes can communicate with each other through the ICL, the priority is honored.
- Allow the node with higher node ID (in case above two options not configured) to take the active role.
- **Range:** 1 through 254

"activeness-probe" on page 1821

Specify the probe destination IP address for activeness determination.

backup-signal-route

Specify the backup signal route to advertise a route with a medium priority. When the HA link is down or the current active node relinquishes active role after any failure, the active signal route is removed from the routing table. The backup overwrites the default routing preference toward the old active node with the medium priority.

- ip-address—IP address for backup signal route
- routing-instance—Routing instance of the backup signal route.

deployment-type

Deployment type of the Services Redundancy Group.

- cloud—Cloud deployment
- hybrid—Hybrid deployment
- routing—Routing deployment
- switching—Switching/default gateway deployment

install-on-failure-route

Divert the traffic by changing the route in a Multinode High Availability setup during a software upgrade. In this case, traffic still traverses through the node and interface remains up.

- *ip-address*—IP address of the route. Mutinode High Availability installs this route to divert the traffic during the upgrade.
- routing-instance *routing-instance*—Routing instance. You must create a dedicated custom virtual router for the route used for diverting traffic during the upgrade.

managed-services

Enable set of services for the specified SRG.

"monitor" on page 10903

Specify to configure the BFD and IP monitoring options.

peer-id

Allows you to choose a specific peer when multiple HA peers are configured globally to the service redundancy group.

preemption

Allow preemption of activeness based on priority. When you configure the activeness priority (1-254) for the SRG1 and enable the preemptive behavior on both nodes, the preempt option ensures that the node with higher activeness priority always remains active after a failover.

prefix-list

Define a named set of address prefixes.

Associate the IP prefix list to the SRG. A prefix list is a listing of IP prefixes that include the local address of IKE gateway. A prefix list is given a name and is configured within the [edit policy-options] configuration hierarchy.

process-packet-on-backup	Enable packet forward engine to forward packets on backup node for the corresponding service redundancy group. When you configure the process packet on back up option, the Packet Forwarding Engine forwards packets on backup node for the corresponding SRG. This configuration processes VPN packets on the backup node even when the node is not active.
services	Enable IPsec VPN service on a particular SRG.
shutdown-on-failure	Configure one or multiple Interfaces which are required to be shut down to isolate the node in case of internal failures or during software upgrades. During software upgrades, you can divert the traffic by closing down interfaces on the node.
"virtual-ip" on page 30761	IP address used for activeness determination and enforcement on the switching side. Required for hybrid and default gateway deployments.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface

Release Information

Statement introduced in Junos OS Release 20.4R1.

Multi SRG1s (SRG1+) support is added in Junos OS Release 22.4R1.

install-on-failure-route option is added in Junos OS Release 22.4R2.

services (System Logging)

IN THIS SECTION

- Syntax | 16800
- Hierarchy Level | 16800
- Description | 16800
- Options | 16801
- Required Privilege Level | 16801
- Release Information | 16801

Syntax

```
services severity-level;
```

Hierarchy Level

```
[edit services service-set service-set-name syslog host hostname]
```

Description

Specify the severity level for system logging messages.

Starting in Junos OS Release 17.4R1, you can configure up to a maximum of four system log servers (combination of local system log hosts and remote system log collectors) for each service set under [edit services service-set *service-set-name*] hierarchy level.

Options

severity-level—Assigns a severity level to the facility. Valid entries are:

- alert—Conditions that should be corrected immediately.
- any—Matches any level.
- critical—Critical conditions.
- emergency—Panic conditions.
- error—Error conditions.
- info—Informational messages.
- notice—Conditions that require special handling.
- warning—Warning messages.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

You can configure multiple system log hosts from Junos OS Release 17.4R1 onwards.

    web-management {...}
    xnm-clear-text {...}
    xnm-ssl {...}
}
```

Hierarchy Level

```
[edit system]
```

Description

Configure the router or switch so that users on remote systems can access the local router or switch through the DHCP server, DTCP over SSH, finger, outbound HTTPS, rlogin, SSH, telnet, Web management, Junos XML protocol SSL, and network utilities. Also, enable configuration of third-party applications developed using the Juniper Extension Toolkit (JET) to run on Junos OS.

The options `dynamic-dns`, `reverse` and `webapi` option is available only for SRX series devices. For further information, see Related Information section.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Options

bbe-stats-service Change the default values of BBE subscriber accounting statistics. The accounting statistics are polled or pushed from the PFE to RE depending on the FPC type, to send to RADIUS server

dtcp-only Allow subscriber DTCP based lawful intercept only

netproxy Enable netproxy service for host OS applications. Netproxy proxies TCP/UDP connections of host OS applications to the netproxy-server running in Junos OS for network access via data and management ports

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

system—To view this statement in the configuration.

system-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

`extension-service` option added in Junos OS Release 16.1 for MX80, MX104, MX240, MX480, MX960, MX2010, MX2020, vMX Series.

`grpc` option added in Junos OS Release 16.2 for MX80, MX104, MX240, MX480, MX960, MX2010, MX2020, vMX Series.

`allow-tcp-forwarding` option added in Junos OS Release 22.2R1.

session-affinity

IN THIS SECTION

- Syntax | 16804
- Hierarchy Level | 16805
- Description | 16805
- Required Privilege Level | 16805
- Release Information | 16805

Syntax

```
session-affinity ipsec
```

Hierarchy Level

```
[edit security flow load-distribution]
```

Description

Enable VPN session affinity. In session affinity feature, we've optimized tunnel redistribution. After tunnel redistribution, the data path might not be optimal, hence we recommend that you enable VPN session affinity to ensure that the data path is optimized. During optimization, the current data path experiences a higher packet delay until it is fully optimized.

This feature is supported on SRX5400, SRX5600, and SRX5800 devices. By default, VPN session affinity is disabled.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.4R5.

Starting with Junos OS Release 15.1X49-D10, IPsec session affinity is supported for IPsec tunnel-based traffic by the SRX5K-MPC3-100G10G (IOC3) and the SRX5K-MPC3-40G10G (IOC3) for SRX5400, SRX5600, and SRX5800 devices through improved flow module and session cache.

- Required Privilege Level | 16807
- Release Information | 16808

Syntax

```
session-drop-hold-down time;
```

Hierarchy Level

[edit security nat source]

Description

Specify the session hold time value to hold the NAT source session without expiring. The session hold time value must be 30 seconds through 28,800 seconds (eight hours).

Required Privilege Level

services—To view this statement in the configuration.

services-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 18.3R1.

session-establishment-hold-time

IN THIS SECTION

- Syntax | 16808
- Hierarchy Level | 16808
- Description | 16808
- Options | 16809
- Required Privilege Level | 16809
- Release Information | 16809

Syntax

```
session-establishment-hold-time seconds;
```

Hierarchy Level

```
[edit protocols iccp],
[edit protocols iccp peer]
```

Description

Specify the time during which an Inter-Chassis Control Protocol (ICCP) connection must be established after IP route reachability between MC-LAG peers is up. When an MC-LAG peer detects IP route reachability to the MC-LAG peer, it tries to connect to it during the session-establishment-hold-time.

> **NOTE**: On QFX and EX Series switches, the default session establishment hold time is 300 seconds. However, the session establishment time must be at least 100 seconds higher than the init delay time. You can optionally update the session establishment time to be 340 seconds and the init delay time to be 240 seconds.

Options

seconds Time (in seconds) within which a successful ICCP connection must be established.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.0.

[edit logical-systems name routing-instances name protocols ldp],
[edit protocols ldp],
[edit routing-instances name protocols ldp]
```

Description

Specify the prefix address of the aggregated group of LDP neighbors for the remote end of the LDP session.

The `session-group` statement is useful when an LDP neighbor is dynamic; for instance, in the case of remote loop free alternate (LFA), a targeted or indirect LDP neighbor is automatically picked from any of the nodes in the network.

The `session-group` statement can also be used for configuring authentication for a prefix group, as LDP authentication for all sessions or authentication at the interface level is not supported.

The remaining statements are explained separately. See CLI Explorer.

Options

name

Session destination address or prefix length.

authentication-algorithm

Authentication algorithm name.

- Values:
  - *aes-128-cmac-96*—Cipher-based Message Authentication Code (AES128) (96 bits)
  - *hmac-sha-1-96*—Hash-based Message Authentication Code (SHA1) (96 bits)
  - *md5*—Message Digest 5

> **NOTE**: MD5 authentication algorithm is supported in both Junos OS and Junos OS Evolved Releases. Whereas, aes-128-cmac-96 and hmac-sha-1-96 algorithms are not supported in Junos OS Evolved Releases

authentication-key

MD5 authentication key.

authentication-key-chain

Authentication key chain name. Authentication key chain option is not supported in Junos OS Evolved Releases.

downstream-on-demand

Configure downstream on demand label distribution mode.

mtu-discovery | no-mtu-discovery

Enable and disable TCP path MTU discovery, respectively.

transport-address *transport-address*

IP address used for TCP sessions to the LDP neighbors that have targeted-LDP adjacencies, and fall under the same IP subnet.

You cannot configure this statement for LDP sessions that have discovered adjacencies.

The transport-address configuration can be rejected at the time of validation, if there is no interface with the configured IP address.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 16.1.

`transport-address` option introduced in Junos OS Releasse 19.1R1 for all platforms.

Starting in Junos OS Evolved 22.1R1 Release, MD5 authentication algorithm is supported for all platforms.

session-id-change-limiter-indirect

IN THIS SECTION

- Syntax | 16814
- Hierarchy Level | 16814
- Description | 16814
- Default | 16814
- Required Privilege Level | 16814
- Release Information | 16814

Syntax

```
forwarding-table {
    session-id-change-limiter-indirect;
}
```

Hierarchy Level

```
[edit routing-options]
```

Description

Creates additional indirect nexthop in the nexthop chain to store session-id changes. When a session-id is changed in any of the indirect nexthop, the Packet Forwarding Engine must reprogram all the parent nodes of the indirect-nexthop. To limit the number of parent nodes that will be re-programmed, an additional indirect nexthop is added in the nexthop chain. This enables the Packet Forwarding Engine to reprogram only the additional indirect-nexthop.

Default

By default, the `session-id-change-limiter-indirect` configuration statement is enabled on the platforms that has Packet Forwarding Engine. To disable the configuration statement, use the `no-session-id-change-limiter` configuration statement.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

    }
}
```

Hierarchy Level

```
[edit services ids rule rule-name term term-name then]
```

Description

Configure the IDS rule session limits for an individual destination or source address or subnet. This protects against network probing attacks and network flooding attacks. This IDS rule can only be assigned to a service set on an MS-MPC.

You can specify limits for specific protocols (ICMP, TCP, and UDP), or specify limits independent of a protocol.

When a session limit is exceeded for a source or destination, packets from the source or to the destination are dropped until the session limit is no longer exceeded.

To specify limits for destination or source subnets rather than individual addresses, include the `aggregation` statement at the `[edit services ids rule rule-name term term-name then]` hierarchy level.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface—To view this statement in the configuration.

session-limit-per-username (Access Profile)

IN THIS SECTION

- Syntax | 16821
- Hierarchy Level | 16822
- Description | 16822
- Options | 16822
- Required Privilege Level | 16822
- Release Information | 16822

Syntax

```
session-limit-per-username number;
```

Hierarchy Level

```
[edit access profile profile-name]
```

Description

Limit the number of active sessions allowed for a username associated with a given access profile. This enables you to control credential sharing by legitimate subscribers. After the limit is configured, existing subscriber sessions for the access profile are tracked as active sessions, as are any new sessions that do not exceed the limit. Requests for sessions that exceed the configured limit are blocked.

Use the `show network-access aaa statistics session-limit-per-username` command to view statistics for active sessions and blocked requests.

You can use the `clear network-access aaa statistics session-limit-per-username username` command as an aid to debugging by clearing the blocked request statistics for any of the following cases:

- For all usernames across all access profiles.
- For a specific username across all access profiles.
- For a specific username in a specific access profile.
- For all usernames in a specific access profile.

Options

number Maximum number of subscriber sessions allowed per username in the access profile.

- **Range:** 1 through 16

Required Privilege Level

- Required Privilege Level | 16827
- Release Information | 16827

Syntax

```
session-memory {
    match {
        threshold threshold;
    }
    then {
        alarm;
        drop-flows;
        log;
        session-aggressive-ageout {
            early-ageout early-ageout;
        }
    }
}
```

Hierarchy Level

```
[edit security resource-manager]
```

Description

Configure resource manager session-memory options to control the behavior of the device based on the sessions that the device is handling.

Options

- `threshold` *`threshold`*-Configure the threshold limit to let `resource-manager` take actions. The range is 1 to 100 percent.
- `session-aggressive-ageout early-ageout` *`seconds`*-When you enable aggressive ageout, sessions with timeout less than the early value, become invalid. Range is 1 through 65,535 seconds.
- `drop-flows`-When you mark a session as a drop-flow, it bypasses the first path for each new packet, which matches the original drop session, for next 4 seconds only. This configuration drops the packets that match the `drop-flows`.
- `log`-This configuration logs messages when the resource threshold is exceeded and falls back under the threshold.
- `alarm`-This configuration sends an SNMP trap when the session usage exceeds the threshold.

Required Privilege Level

security—To view this in the configuration.

security-control—To add this to the configuration.

    }
}
```

Hierarchy Level

```
[edit access profile profile-name]
```

Description

(MX Series and SRX Series Firewalls) Define options to place limits on subscriber access based on how long the session has been up, how long the user has been inactive, or both.

(MX Series) Define options to modify a subscriber username at login based on the subscriber's access profile.

(MX Series) Specify characteristics related to policy and charging control (PCC) rules, such as the PCEF profile that contains the rules, service sets to process the rules, and service filters for the service sets.

Options

client-idle-timeout

Specify the grace period that begins after an authenticated user terminates all sessions and connections. Authentication is not required if a new connection is initiated during the grace period by the same user.

During this period, the router determines whether the subscriber is inactive by monitoring data traffic, both upstream from the user (ingress) and downstream to the user (egress). Control traffic is ignored. The subscriber is not considered idle as long as data traffic is detected in either direction. When no traffic is detected for the duration of the idle time out, non-DHCP subscribers (such as L2TP or PPP) are gracefully logged out, similarly to a RADIUS-initiated disconnect or a CLI-initiated logout; DHCP subscribers are disconnected.

When you additionally configure the related `client-idle-timeout-ingress-only` statement (MX Series only), the router monitors only ingress traffic to determine whether the subscriber is inactive; it does not monitor any egress traffic. The related `client-session-timeout` statement terminates the subscriber session when the session timeout expires regardless of user activity.

Client idle timeouts are most often used for residential services rather than business services. The most practical use case for this timeout is in a PPP access model. It is not practical for DHCP or DHCPv6 subscribers.

Although you can use the `client-idle-timeout` statement for dynamically configured subscriber VLANs, this configuration is useful only in limited circumstances (such as IP over Ethernet without DHCP and with fixed addresses) and is not typically used. If you do use the idle timeout for VLANs, the timeout period starts when the VLAN is instantiated. It

resets when a client session is created or an existing session is reactivated. When no traffic is detected on an authenticated VLAN for the duration of the timeout, the VLAN is considered inactive and is deleted. If no client sessions are ever created on the VLAN, then the VLAN is removed when the timeout expires.

- **Default:** The timeout is not configured.
- **Values:** *minutes*—Number of minutes of idle time that elapse before the session is terminated. The value that you specify must be determined locally with consideration of the services and policies that you offer.
- **Range:** 10 through 1440 minutes

client-idle-timeout-ingress-only

Specify that only ingress traffic is monitored for subscriber idle timeout processing for the duration of the idle timeout period that you specify with the `client-idle-timeout` statement. If no ingress traffic is received for the duration of the timeout, then the subscriber is gracefully logged out (non-DHCP subscribers) or disconnected (DHCP subscribers).

If you configure `client-idle-timeout` alone, then both ingress and egress traffic are monitored during the idle timeout. Monitoring only ingress traffic is useful in cases where the LNS sends traffic to the remote peer even when the peer is not up, such as when the LNS does not have PPP keepalives enabled and therefore does not detect that the peer is not up. Because the LAC monitors both ingress and egress traffic by default, in this situation it receives the egress traffic from the LNS and either does not log out the subscriber or delays detection of inactivity until the egress traffic ceases. When you specify that only ingress traffic is monitored in this case, the LAC can detect that the peer is inactive and then initiate logout.

client-session-timeout

Specify the amount of time after which user sessions are terminated, regardless of user activity (also known as a forced or hard authentication timeout).

Alternatively, when you want subscribers to be identified as inactive before they are terminated, use the related statements, `client-idle-timeout` and `client-idle-timeout-ingress-only`. Use `client-idle-timeout` alone to specify a period of time during which both ingress and egress subscriber data traffic is monitored; if no traffic is detected for the duration of the period, the subscriber is considered inactive and is terminated. Add the `client-idle-timeout-ingress-only` statement to monitor only ingress traffic for the duration of the timeout set with the `client-idle-timeout statement`.

BEST PRACTICE: We recommend that you do not configure a session timeout for subscribers receiving voice services. Because the session timeout is a simple time-based timeout, it is likely to interrupt subscribers actively using a voice service and terminate their calls unexpectedly (from

the subscriber viewpoint). This result is a particular concern for emergency services calls.

Client session timeouts are most often used for residential services rather than business services. The most practical use case for this timeout is in a PPP access model when no voice services are offered. For DHCP or DHCPv6 subscribers, the session timeout is used as the DHCP lease timer if no other lease time configuration is present.

Although you can use the `client-session-timeout` statement for dynamically configured subscriber VLANs, this configuration is useful only in limited circumstances (such as IP over Ethernet without DHCP and with fixed addresses) and is not typically used. If you do use the session timeout for VLANs, the timeout period starts when the VLAN is instantiated.

- **Default:** The timeout is not configured.
- **Values:** *minutes*—Number of minutes after which user sessions are terminated. The value that you specify must be determined locally with consideration of the services and policies that you offer.
- **Range:** 1 through 527040 minutes

[edit routing-options validation group group-name]
```

Description

Configure a TCP session with a resource public key infrastructure (RPKI) cache server. The router-to-cache transport protocol is carried using a TCP session to a configurable port. Caches are organized in groups. The Junos OS implementation supports up to 63 sessions per group and both IPv4 and IPv6 address families.

The maximum number of sessions in a group is two, by default, and is configurable. If the number of sessions in a group exceeds the `max-sessions` value, the connections are established in order by `preference` value. A numerically higher preference results in a higher probability for session establishment. The order of session establishment is random among sessions with equal preferences.

Options

server-ip-address	Specify the IP address of the RPKI cache server.
database *database-name*	Specify a named validation database.
hold-time *seconds*	Specify the length of time in seconds that the session between the routing device and the RPKI cache server is to be considered operational without any activity. After the hold time expires, the session is dropped.

Receiving any protocol data unit (PDU) from the cache server resets the hold timer. The hold time must be configured to be at least twice the value configured on the `refresh-time` statement. If the hold time expires, the session is considered to be down. This, in turn, triggers a session restart event. During a session restart, the routing device attempts to start a session with the cache server that has the numerically highest `preference` value.

- **Range:** 10 through 3600 seconds. We recommend that you configure the hold time to atleast twice the refresh time.
- **Default:** 600 seconds

local-address *local-ip-address*

Configure a local IP address of the session to be used for the outgoing connection to the RPKI cache server. If the local cache server has inbound firewall filtering, it might be necessary to specify a local IP address to use for this session.

port *port-number*

Configure an alternative TCP port number to be used for the outgoing connection to the cache server. The well-known resource public key infrastructure (RPKI) port is TCP port 2222. For a given deployment, an RPKI cache server might listen on some other TCP port number. If so, configure the alternative port number with this statement.

- **Default:** 2222

preference *number*

Configure the preference number for the RPKI cache server. Each cache server has a static preference. Higher preferences are preferred. During a session start or restart, the device attempts to start a session with the cache server that has the numerically highest preference. The device connects to multiple cache servers in preference order.

- **Range:** 1 through 255
- **Default:** 100

record-lifetime *seconds*

Configure the amount of time that route validation (RV) records learned from an RPKI cache server remain valid after the session to the cache server goes down. RV records expire if the session to the cache server goes down and remains down for the time configured.

- **Range:** 60 (one minute) through 604800 (one week). We recommend that you configure this record lifetime atleast twice the refresh time or greater. If you set this value to 60 seconds or lower, it might trigger very frequent refreshes causing higher CPU usage.
- **Default:** 3600 seconds (one hour)

refresh-time *seconds*

Configure a liveliness check interval for a configured resource public key infrastructure (RPKI) cache server. After every period of time configured on the `refresh-time` statement (in seconds), a serial query protocol data unit (PDU) with the last known serial number is transmitted. The value configured on the `refresh-time` statement cannot be longer than half of the value configured on the `hold-time` statement.

- **Range:** 1 through 1800 seconds
- **Default:** 300 seconds

The remaining statement is explained separately. See CLI Explorer.

```

Hierarchy Level

```
[edit logical-systems name protocols ldp],
[edit logical-systems name routing-instances name protocols ldp],
[edit protocols ldp],
[edit routing-instances name protocols ldp]
```

Description

Configure LDP session parameters by specifying the session destination address.

Options

session-address Session destination address.

authentication-algorithm Authentication algorithm name.

- Values:
  - `aes-128-cmac-96`—Cipher-based Message Authentication Code (AES128) (96 bits).
  - `hmac-sha-1-96`—Hash-based Message Authentication Code (SHA1) (96 bits).
  - `md5`—Message Digest 5.

authentication-key MD5 authentication key.

authentication-key-chain Key chain name.

downstream-on-demand Configure downstream on demand label distribution mode.

mtu-discovery Enable TCP path MTU discovery.

no-mtu-discovery Disable TCP path MTU discovery.

transport-address *transport-address* IP address used for TCP sessions to the LDP neighbors that have targeted-LDP adjacencies.

You cannot configure this statement for LDP sessions that have discovered adjacencies.

The transport-address configuration can be rejected at the time of validation, if there is no interface with the configured IP address.

Required Privilege Level

session-scan

IN THIS SECTION

- Syntax | 16847
- Hierarchy Level | 16847
- Description | 16848
- Required Privilege Level | 16848
- Release Information | 16848

Syntax

```
session-scan;
```

Hierarchy Level

```
[edit security dynamic-address address-name name]
```

Description

Session scan provides an efficient method to traverse the session table to check and update each session. You can configure the `session-scan` option at two levels, entry level and module level. The entry level `session-scan` requests session scan only when the configured entries have the new addresses, while the module level takes all the entries belong to dynamic address into the scope. By default, the `session-scan` for dynamic address are disabled due to the session scan is CPU intensive.

The session scan checks all sessions source pool ID and ensures all session associated with modified pool can be removed. Session scan consumes more CPU cycle and is better not to trigger the session scan frequently. When one pool gets modified, session scan is not immediately triggered. When the modified pool number is greater than or equal to 1024 or becomes more than ten seconds, the session scan is triggered. The 10 second delay is designed to merge the session scan. For example, the first pool gets modified and after five seconds the second pool is modified, then after five seconds the session scan gets triggered, and thus for first pool and second pool the session scan gets merged together.

           init-phase-failure value;
           auth-phase-failure value;
        }
        discard-duplicate;
        max-count value;
        thresholds {
            send-cookie count;
            reduce-timeout count timeout seconds;
        }
     }
}
```

Hierarchy Level

```
[edit security ike]
```

Description

Defines IKE session configuration.

In the configuration hierarchy, you can set the system level parameters of the IKE session to manage the behavior of the negotiations with the remote peer. You configure these settings to control high load scenarios.

Options

full-open

Define the full open IKE session parameters.

half-open

Define the half open IKE session parameters.

incoming-exchange-max-rates

Define the full open IKE session incoming exchange maximum rates.

You can use this parameter to set the maximum rates for various exchanges initiated by the remote peer after establishing an IKE SA.

ike-rekey *value*

Specify the value of the incoming peer initiated IKE rekey maximum rate.

The rate is applicable on a per peer basis.

- Format: Specify the value in [*count*]/[*duration in seconds*] format.
- Value: Range is [1 – 86400] / [1 – 86400].

ipsec-rekey *value*

Specify the value of the incoming peer initiated IPsec SA rekey maximum rate.

The rate is applicable on a per tunnel basis.

- Format: Specify the value in [*count*]/[*duration in seconds*] format.
- Value: Range is [1 – 86400] / [1 – 86400].

keepalive *value*

Specify the value of the incoming peer initiated keepalive, also knows as DPD, maximum rate.

The rate is applicable on a per peer basis.

- Format: Specify the value in [*count*]/[*duration in seconds*] format.
- Value: Range is [1 – 86400] / [1 – 86400].

backoff-timeouts

Define the half-open IKE session backoff timeouts.

You set these timeouts to allow some duration for the remote peer to back off in the event of a session initiation failure, ensuring that the same peer cannot initiate a new session initiation request immediately during that period. After the backoff timeout, the peer can initiate a new session. The scope is applicable at global level and not per peer level.

auth-phase-failure *value*

Specify the backoff timeout when there's a failure during the IKE_AUTH phase.

- Value: Range is 1 - 180 seconds.
- Default: Disabled

init-phase-failure *value*

Specify the backoff timeout when there's a failure during the SA_INIT phase.

- Value: Range is 1 - 180 seconds.
- Default: Disabled

discard-duplicate

Discard duplicate IKE session initiation requests from the peer.

Discard the IKE initiation requests without sending any response, when the half open IKE SA is already present for the same remote peer. The scope is applicable at global level and not per peer level.

- Default: Disabled

max-count *value*

Maximum numbers of half open IKE sessions where the local end is the responder.

The scope is applicable at global level and not per peer level.

- Value: Range is 1-10000
- Default: 300

thresholds

Define the half open IKE session thresholds.

You can set the limits on half open IKE SA count for actions against new a connection. The values denote percentage of the total half open IKE SAs. The scope is applicable at global level and not per peer level.

If you set the `max-count` explicitly, it automatically disables all thresholds unless you configure explicitly.

reduce-timeout *count* timeout *seconds*

Specify the minimum number of half open IKE sessions for enforcing reduce-timeout action at `reduce-timeout` *`count`*.

Set a limit from which you can reduce the lifetime of new half open IKE SAs.

- Value: Range is 1 - 10000.
- Default: Disabled

Specify the reduced timeout value at `timeout` *`seconds`*.

- Value: Range is 1 - 180 seconds.
- Default: Disabled

send-cookie *count*

Specify the minimum number of half open IKE sessions for enforcing cookie action.

Specify the threshold limit from which the responder requests remote peers to retry session initiation with a cookie sent back to the peer in the initial response.

- Value: Range is 1 - 10000.
- Default: 250.

timeout *seconds*

Specify the half open IKE session timeout.

This is the lifetime value of a half-open IKE SA that is applicable on the responder for the new sessions. For the existing sessions where there is no explicit configuration, the value is set to default. Initiator continues to use 60 seconds timeout value. The scope is applicable at global level and not per peer level.

- Value: Range is 1 - 180 seconds.
- Default: 60 seconds

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

    session-limit number;
}
```

Hierarchy Level

```
[edit system services web-management]
```

Description

Configure parameters for web-management sessions. Web management allows for configuration of the SRX Series Firewall using the J-Web interface. You can configure the idle-timeout parameter for web-management sessions and the maximum number of concurrent sessions.

Options

idle-timeout ***minutes***

Configure in minutes the time-out parameter for all web-management sessions. The idle-timeout parameter specifies the length of time that a session can be idle before it is terminated.

- **Default:** 1440
- **Range:** 1 to 1440

session-limit *number*

Configure the maximum allowed number of concurrent web management sessions. By default, an unlimited number of users can log in to the J-Web interface on a Juniper Networks device, and each session remains open for 24 hours (1440 minutes).

- **Default:** unlimited
- **Range:** 1 to 1024

Required Privilege Level

Displaying the Current Configuration

set chassis cluster cluster-id node node-number reboot

IN THIS SECTION

- Syntax | 16861
- Description | 16862
- Options | 16862
- Required Privilege Level | 16862
- Output Fields | 16862
- Release Information | 16863

Syntax

```
set chassis cluster cluster-id cluster-id node  node-number reboot
```

Description

Sets the chassis cluster identifier (ID) and node ID on each device, and reboots the devices to enable clustering. The system uses the chassis cluster ID and chassis cluster node ID to apply the correct configuration for each node (for example, when you use the `apply-groups` command to configure the chassis cluster management interface). The chassis cluster ID and node ID statements are written to the EPROM, and the statements take effect when the system is rebooted.

Setting a cluster ID to 0 is equivalent to disabling a cluster. A cluster ID greater than 15 can only be set when the fabric and control link interfaces are connected back-to-back.

> **NOTE**: If you have a cluster set up and running with an earlier release of Junos OS, you can upgrade to Junos OS Release 12.1X45-D10 or later and re-create a cluster with cluster IDs greater than 16. If for any reason you decide to revert to the previous version of Junos OS that did not support extended cluster IDs, the system comes up with standalone devices after you reboot. If the cluster ID set is less than 16 and you roll back to a previous release, the system comes back with the previous setup.

Options

cluster-id *cluster-id*

Identifies the cluster within the Layer 2 domain.

- **Range:** 0 through 255

node *node*

Identifies a node within a cluster.

- **Range:** 0 through 1

reboot

reboot the specified devices to configure the chassis cluster.

Required Privilege Level

maintenance

Output Fields

When you enter this command, you are provided feedback on the status of your request.

Release Information

Support for extended cluster identifiers (more than 15 identifiers) added in Junos OS Release 12.1X45-D10.

- Syntax (TX Matrix Plus Router) | 16865
- Description | 16866
- Options | 16866
- Required Privilege Level | 16867
- Output Fields | 16867
- Sample Output | 16867
- Release Information | 16868

Syntax

```
set chassis display message "message"
<permanent>
```

Syntax (TX Matrix Router)

```
set chassis display message "message" (lcc number / scc)
 <permanent>
```

Syntax (TX Matrix Plus Router)

```
set chassis display message “message ” (fpc-slot slot-number | lcc number /  sfc number)
 <permanent>
```

Description

Display or stop a text message on the craft interface display, which is on the front of the router, or on the LCD panel display on the switch. The craft interface alternates the display of text messages with standard craft interface messages three times, switching between messages every 60 seconds.

> **NOTE**: On T Series routers, when this command is executed with the **permanent** option, the display of the text message alternates with that of the standard craft interface message continuously every 60 seconds.

By default, on both the router and the switch, the text message is displayed for 5 minutes. The craft interface display has four 20-character lines. The LCD panel display has two 16-character lines, and text messages appear only on the second line.

Options

"*message*"
Message to display. On the craft interface display, if the message is longer than 20 characters, it wraps onto the next line. If a word does not fit on one line, the entire word moves down to the next line. Any portion of the message that does not fit on the display is truncated. An empty pair of quotation marks (“ ”) deletes the text message from the craft interface display. On the LCD panel display, the message is limited to 16 characters.

fpc-slot *slot-number*
(TX Matrix Plus routers and EX4200 and QFX Series only) On the router or switch, display the text message on the craft interface for a specific Flexible PIC Concentrator (FPC). Replace *slot-number* with a value from **0** through **31**. On the switch, display the text message for a specific member of a Virtual Chassis, where **fpc-slot *slot-number*** corresponds to the member ID. Replace ***slot-number*** with a value from **0** through **9**. On the QFX Series, the *slot-number* is always **0**. On a TX Matrix Plus router with 3D SIBs replace *slot-number* with a value from `0` through `63`.

lcc *number*
(TX Matrix router and TX Matrix Plus router only) (Optional) Line-card chassis number.

Replace *number* with the following values depending on the LCC configuration:

- 0 through 3, when T640 routers are connected to a TX Matrix router in a routing matrix.
- 0 through 3, when T1600 routers are connected to a TX Matrix Plus router in a routing matrix.

- 0 through 7, when T1600 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.
- 0, 2, 4, or 6, when T4000 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.

permanent (Optional) Display a text message on the craft interface display or LCD panel display permanently.

scc (TX Matrix routers only) Display the text message on the craft interface display of the TX Matrix router (switch-card chassis).

sfc *number* (TX Matrix Plus routers only) Display the text message on the craft interface display of the TX Matrix Plus router (or switch-fabric chassis).

Required Privilege Level

clear

Output Fields

See show chassis craft-interface for an explanation of output fields.

Sample Output

set chassis display message (Creating)

The following example shows how to set the display message and verify the result:

```
user@host> set chassis display message "NOC
contact Dusty (888) 555-1234"
message sent
```

```
user@host> show chassis craft-interface
Red alarm:     LED off, relay off
Yellow alarm:  LED off, relay off
Host OK LED:   On
Host fail LED: Off
FPCs     0  1  2  3  4  5  6  7
-------------------------------
```

```
Green  ..  *..  *  *.
Red    ........
LCD screen:
     +--------------------+
     |NOC contact Dusty   |
     |(888) 555-1234      |
     +--------------------+
```

set chassis display message (Deleting)

The following example shows how to delete the display message and verify that the message is removed:

```
user@host> set chassis display message ""
message sent

user@host> show chassis craft-interface
Red alarm:     LED off, relay off
Yellow alarm:  LED off, relay off
Host OK LED:   On
Host fail LED: Off
FPCs     0  1  2  3  4  5  6  7
-------------------------------
Green  ..  *..  *  *.
Red    ........
LCD screen:
     +--------------------+
     |host                |
     |Up: 0+17:05:47      |
     |                    |
     |Temperature OK      |
     +--------------------+
```

Release Information

Command introduced before Junos OS Release 7.4.

sfc option for TX Matrix Plus router introduced in Junos OS Release 9.6.

set chassis virtual-chassis

IN THIS SECTION

- Syntax | 16869
- Description | 16869
- Options | 16870
- Required Privilege Level | 16870
- Sample Output | 16870
- Release Information | 16870

Syntax

```
set chassis virtual-chassis
<disable>
<local>
```

Description

Set the EX8200 switch into Virtual Chassis mode.

An EX8200 switch cannot be a member switch in an EX8200 Virtual Chassis until the switch is in Virtual Chassis mode.

This command is not needed when configuring an EX3300 Virtual Chassis, EX4200 Virtual Chassis, EX4500 Virtual Chassis, or a mixed EX4200 and EX4500 Virtual Chassis.

Options

none Set the internal Routing Engines into Virtual Chassis mode.

disable Disable Virtual Chassis mode for all internal REs on the switch.

local Set the Routing Engine that you are currently logged in to into Virtual Chassis mode.

Required Privilege Level

view

Sample Output

set chassis virtual-chassis

```
user@switch> set chassis virtual-chassis
This will reboot the RE(s)
Do you want to continue ? [yes,no] (no) yes
```

Release Information

Command introduced in Junos OS Release 10.4.

Configuring an EX8200 Virtual Chassis (CLI Procedure)

set cli complete-on-space

IN THIS SECTION

Syntax | 16871

- Description | 16871
- Options | 16871
- Required Privilege Level | 16871
- Output Fields | 16871
- Sample Output | 16872
- Release Information | 16872

Syntax

```
set cli complete-on-space (off | on)
```

Description

Set the command-line interface (CLI) to complete a partial command entry when you type a space or a tab. This is the default behavior of the CLI.

Options

off Turn off command completion.

on Allow either a space or a tab to be used for command completion.

Required Privilege Level

view

Output Fields

When you enter this command, you are provided feedback on the status of your request.

Sample Output

set cli complete-on-space

In the following example, pressing the Spacebar changes the partial command entry from **com** to **complete-on-space**. The example shows how adding the keyword **off** at the end of the command disables command completion.

```
user@host> set cli com<Space>
user@host>set cli complete-on-space off
Disabling complete-on-space
```

Release Information

Command introduced before Junos OS Release 7.4.

set cli idle-timeout

IN THIS SECTION

- Syntax | 16874
- Description | 16874
- Options | 16874
- Required Privilege Level | 16874
- Output Fields | 16875
- Sample Output | 16875
- Release Information | 16875

Syntax

```
set cli idle-timeout <minutes>
```

Description

Set the maximum time that an individual session can be idle before the user is logged off the router or switch. `set cli idle-timeout` holds good only for the session in use when you enter it. If you need to configure the idle timeout permanently for all the CLI sessions, then configure the `idle-timeout` statement at the `[edit system login]` hierarchy level.

Options

minutes (Optional) Maximum idle time. The range of values, in minutes, is 0 through 100,000. If you do not issue this command, and the user's login class does not specify this value, the user is never forced off the system after extended idle times. Setting the value to 0 disables the timeout.

Required Privilege Level

view

Output Fields

When you enter this command, you are provided feedback on the status of your request.

Sample Output

set cli idle-timeout

```
user@host> set cli idle-timeout 60
Idle timeout set to 60 minutes
```

Release Information

Command introduced before Junos OS Release 7.4.

set cli screen-length

IN THIS SECTION

- Syntax | 16880
- Description | 16880
- Options | 16880
- Required Privilege Level | 16880
- Release Information | 16881

Syntax

```
set cli screen-length length
```

Description

Set terminal screen length.

```
user@host> set cli screen-length 75
Screen length set to 75
```

Options

length—Number of lines of text that the terminal screen displays. The range of values, in an integer number of lines, 0 through 10,000 (except 1 in range). The value 0 sets no screen length. It also sets the `restart-on-upgrade` command off. The default value is 24.

The point at which the `---(more)---` prompt appears on the screen is a function of this setting and the settings for the `set cli screen-width` and `set cli terminal` commands.

Syntax

```
set date (date-time | ntp <ntp-server> <key authentication-key number> <servers> <source-address
source-address>)
```

Description

Set the date and time.

```
user@host> set date ntp
21 Apr 17:22:02 ntpdate[3867]: step time server 172.17.27.46 offset 8.759252 sec
```

Options

- *date-time*—Specify date and time in one of the following formats:
  - *YYYYMMDDHHMM.SS*
  - "*month DD, YYYY HH:MM*(am | pm)"

  NOTE: In Junos OS Evolved, the date and time will be set only on the node where the command is issued.

- ntp—Configure the router to synchronize the current date and time setting with a Network Time Protocol (NTP) server.

  NOTE: In Junos OS Evolved, if the ntpd server is running, the `set date ntp` command fails with the following error message: `error: ntpd is already running`. To use this command, you must first stop the ntpd server

- *ntp-server*—(Optional) Specify the IP address of one or more NTP servers.

- `key` *`authentication-key number`*—(Optional) Specify a key number to authenticate the NTP server used to synchronize the date and time. You must specify the same key number used to authenticate the server configured at the [`edit system ntp authentication-key` *`number`*] hierarchy level.
- `servers`—(Optional) Specify the IP address of one or more NTP servers.
- `source-address` *`source-address`*—(Optional) Specify the source address that is used by the router to contact the remote NTP server.

Required Privilege Level

- Release Information | 16889

Syntax

```
set date ntp <servers | force | key key | node node-number | routing-instance routing-instance-name | source-address source-address>
```

Description

Set the date and local time. If reject mode is enabled and the system rejected the update from the NTP server because it exceeds the configured threshold value, an administrator has two options to overrule the reject mode action: manually set the date and time in *YYYYMMDDhhmm.ss* format, or force synchronization of device time with the NTP server update by specifying the **force** option.

Options

servers	Specify the IP address of one or more NTP servers.
force	Force system date and time to update to NTP server values. The device date and time are synchronized with the NTP proposed date and time even if reject is set as the action and the difference between the device time and NTP proposed time exceeds the default or the configured threshold value.

key *key*	Specify a key number to authenticate the NTP server used to synchronize the date and time. You must specify the same key number used to authenticate the server, configured at the [`edit system ntp authentication-key` *number*] hierarchy level.
node *node-name*	Specify system date and time using NTP servers on specific node.
routing-instance *routing-instance-name*	Specify the routing instance through which server is available.
source-address *source-address*	Specify the source address that the SRX Series devices use to contact the remote NTP server.

Required Privilege Level

view

Output Fields

set-dont-fragment-bit (Services IPsec VPN)

IN THIS SECTION

- Syntax | 16890
- Hierarchy Level | 16890
- Description | 16890
- Required Privilege Level | 16891
- Release Information | 16891

Syntax

```
set-dont-fragment-bit;
```

Hierarchy Level

```
[edit services ipsec-vpn rule rule-name term term-name then]
```

Description

Configure the do not fragment (DF) bit in only the outer header of the IPsec packet and leave the inner header unmodified. If the encapsulated packet size exceeds the tunnel maximum transmission unit (MTU), the packet is fragmented before encapsulation. These settings apply for static endpoint tunnels and not for dynamic tunnels, for which you need to include the `set-dont-fragment-bit` statement at the `[edit services service-set service-set-name ipsec-vpn-options]` hierarchy level to set the DF bit in the outer header of the IPv4 packets that enter the dynamic IPsec tunnel. This functionality is supported on MX Series routers with MS-MICs and MS-MPCs.

By default, this statement is disabled on MS-MICs and MS-MPCs (the DF bit value is not configured in the outer header by default).

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 14.1.

Configuring Local System Logging for Next Gen Services

stream (Next Gen Services Service-Set Remote System Logging) | **28631**

severity (Security IDP Custom Attack)

IN THIS SECTION

- Syntax | **16902**
- Hierarchy Level | **16902**
- Description | **16902**
- Options | **16902**
- Required Privilege Level | **16902**
- Release Information | **16903**

Syntax

```
severity (critical | info | major | minor | warning);
```

Hierarchy Level

```
[edit security idp custom-attack attack-name]
```

Description

Select the severity that matches the lethality of the attack object on your network.

Options

You can set the severity level to the following levels:

- `critical`—Contains attack objects matching exploits that attempt to evade detection, cause a network device to crash, or gain system-level privileges.
- `warning`—Contains attack objects matching exploits that attempt to obtain noncritical information or scan a network with a scanning tool.
- `major`—Contains attack objects matching exploits that attempt to disrupt a service, gain user-level access to a network device, or activate a Trojan horse previously loaded on a device.
- `minor`—Contains attack objects matching exploits that detect reconnaissance efforts attempting to access vital information through directory traversal or information leaks.
- `info`—Contains attack objects matching normal, harmless traffic containing URLs, DNS lookup failures, SNMP public community strings, and Peer-to-Peer (P2P) parameters. You can use informational attack objects to obtain information about your network.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.3.

severity (Security IDP Dynamic Attack Group)

IN THIS SECTION

- Syntax | 16903
- Hierarchy Level | 16903
- Description | 16903
- Options | 16903
- Required Privilege Level | 16904
- Release Information | 16904

Syntax

```
severity {
    values [critical info major minor warning];
}
```

Hierarchy Level

```
[edit security idp dynamic-attack-group dynamic-attack-group-name filters]
```

Description

Specify a severity filter to add attack objects based on the attack severity levels.

Options

`values`—Name of the severity filter. You can select from the following severity:

- `critical`—The attack is a critical one.
- `info`—Provide information of attack when it matches.
- `major`—The attack is a major one.
- `minor`—The attack is a minor one.
- `warning`—Issue a warning when attack matches.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.3.

severity (Security IDP IPS Rulebase)

IN THIS SECTION

- Syntax | 16904
- Hierarchy Level | 16905
- Description | 16905
- Options | 16905
- Required Privilege Level | 16905
- Release Information | 16905

Syntax

```
severity (critical | info | major | minor | warning);
```

Hierarchy Level

```
[edit security idp idp-policy policy-name rulebase-ips rule rule-name then]
```

Description

Set the rule severity levels in logging to support better organization and presentation of log records on the log server. You can use the default severity settings of the selected attack object, or choose a specific severity for your rule. The severity you configure in the rules overrides the inherited attack severity.

Options

You can set the severity level to the following levels:

- `critical`—2
- `info`—3
- `major`—4
- `minor`—5
- `warning`—7

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.2.

severity (Security Log)

IN THIS SECTION

- Syntax | 16906
- Hierarchy Level | 16906
- Description | 16906
- Options | 16906
- Required Privilege Level | 16907
- Release Information | 16907

Syntax

```
severity (alert | critical | debug | emergency | error | info | notice | warning)
```

Hierarchy Level

```
[edit security log stream stream-name]
[edit logical-systems name security log stream stream-name]
[edit tenants tenant-name security log stream stream-name]
```

Description

Set severity threshold for security logs.

Options

- `alert`— Conditions that require immediate attention.
- `critical`—Critical conditions.
- `debug`—Information normally used in debugging.
- `emergency`—Conditions that cause security functions to stop.

- `error`—General error conditions.
- `info`—Information about normal security operations.
- `notice`—Nonerror conditions that are of interest.
- `warning`—General warning conditions.
- **Default:** debug.

Required Privilege Level

security—To view this statement in the configuration.

security-control—To add this statement to the configuration.

Release Information

Statement modified in Junos OS Release 9.2.

The [edit `logical-systems` *name* security log stream *stream-name*] and [edit `tenants` *tenant-name* security log stream *stream-name*] hierarchy levels introduced in Junos OS Release 19.1R1.

```

Hierarchy Level

```
[edit protocols]
```

Description

Configure sFlow technology to continuously monitor traffic at wire speed on specified interfaces simultaneously. sFlow data can be used to provide network traffic visibility information. You can configure sample size of the raw packets in the sFlow record. The range varies from 128 bytes to 512 bytes.

Default

sFlow technology is disabled by default.

Required Privilege Level

routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.3.

`dscp` and `forwarding-class` options introduced in Junos OS Release 19.1R1, for PTX routers and QFX switches (previously introduced for MX Series).

`sample-size` option introduced in Junos OS Evolved Release 23.1R1, for PTX routers.

sfm (Chassis)

IN THIS SECTION

- Syntax | 16912
- Hierarchy Level | 16912
- Description | 16912
- Options | 16912
- Required Privilege Level | 16913
- Release Information | 16913

Syntax

```
sfm slot-number power off;
```

Hierarchy Level

```
[edit chassis]
```

Description

For routers with SFMs, configure an SFM to stay offline.

By default, if you use the **request chassis sfm** CLI command to take an SFM offline, the SFM will attempt to restart when you enter a **commit** CLI command. To prevent a restart, configure an SFM to stay offline. This feature is useful for repair situations. The SFM remains offline until you delete this statement.

Options

slot-number—Slot number in which the SFM is installed.

power off—Take the SFM offline and configure it to remain offline.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

RELATED DOCUMENTATION

sfm (Chassis Redundancy)

IN THIS SECTION

- Syntax | 16913
- Hierarchy Level | 16914
- Description | 16914
- Default | 16914
- Options | 16914
- Required Privilege Level | 16914
- Release Information | 16914

Syntax

```
sfm slot-number (always | preferred);
```

Hierarchy Level

```
[edit chassis redundancy]
```

Description

On M40e and M160 routers, configure which Switching and Forwarding Module (SFM) is the primary and which is the backup.

Default

By default, the SFM in slot 0 is the primary and the SFM in slot 1 is the backup.

Options

slot-number—Specify which slot is the primary and which is the backup. On the M40e router, ***slot-number*** can be 0 or 1. On the M160 router, ***slot-number*** can be 0 through 3.

always—Define this SFM as the sole device.

preferred—Define this SFM as the preferred device of at least two.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

IN THIS SECTION

- Syntax | 16915
- Hierarchy Level | 16915
- Description | 16915
- Default | 16915
- Required Privilege Level | 16916
- Release Information | 16916

Syntax

```
sfpplus {
    pic-mode mode;
}
```

Hierarchy Level

```
[edit chassis fpc slot pic pic-number]
```

Description

Configure the operating mode for the specified port on the SFP+ uplink module on the EX3200 or EX4200 switch.

The remaining statement is explained separately. See CLI Explorer.

Default

By default, the SFP+ uplink module operates in the 10-gigabit mode and supports SFP+ transceivers.

> **NOTE**: The SFP+ uplink module provides two ports for 10-gigabit small form-factor pluggable (SFP+) transceivers when configured to operate in 10-gigabit mode or four ports for 1-gigabit small form-factor pluggable (SFP) transceivers when configured to operate in 1-gigabit mode.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 9.4.

    ssh-connection-linger;
    ssh-log-verbose;
    ssh-passphrase;
}
```

Hierarchy Level

```
[edit access ocs partition partition-name]
```

Description

The data backup for OCS using the SFTP protocol to store data on a remote server.

Options

accumulation-timeout *seconds*

The file accumulation time since the first CCR-GY-T was submitted. The maximum time is 30 seconds.

accumulation-count *messages*

The number of requests that are past file account count. The maximum accumulation count is 2000 messages.

accumulation-size *bytes*	The file once its size has reached the accumulation size limit. The maximum accumulation size is 3000000 bytes.
logical-system	The logical system to be used by sftp.
retry-interval *seconds*	Every failed write operation is retried after this interval until backup timeout is accumulated. The maximum retry interval is 1200 seconds.
response-timeout *seconds*	The timeout on individual SFTP command response. The maximum response timeout is 60 seconds.
routing-instance	The SFTP service connection context for the routing instance.
address	The address of SFTP server
port	The port number. The default port number is 22.
directory	The directory name.
file-prefix *prefix*	The prefix for the file.
node-ipv4-address	The IPv4 address of the sending node.
node-ipv6-address	The IPv6 address of the sending node.
ssh-login	The login name on SFTP server, may include %h and/or %r similar to directory.
ssh-connection-linger	The time to keep existing ssh connection idle state.
ssh-log-verbose	The verbose logs to be collected from ssh session.
ssh-passphrase	The password or later passphrase.

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 18.1.

sglimit

IN THIS SECTION

- Syntax | **16919**
- Hierarchy Level | **16920**
- Description | **16920**
- Options | **16920**
- Required Privilege Level | **16920**
- Release Information | **16920**

Syntax

```
sglimit {
    family (inet | inet6) {
        log-interval seconds;
        maximum limit;
        threshold value;
    }
    log-interval seconds;
    maximum limit;
    threshold value;
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name protocols pim],
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols pim],
[edit protocols pim ],
[edit routing-instances routing-instance-name protocols pim]
```

Description

Configure a limit for the number of accepted (*,G) and (S,G) PIM join states.

> **NOTE**: The maximum limit settings that you configure with the `maximum` and the `family (inet | inet6) maximum` statements are mutually exclusive. For example, if you configure a global maximum PIM join state limit, you cannot configure a limit at the family level for IPv4 or IPv6 joins. If you attempt to configure a limit at both the global level and the family level, the device will not accept the configuration.

Options

`family (inet | inet6)`—(Optional) Specify either IPv4 or IPv6 join states to be counted towards the configured join state limit.

- **Default:** Both IPv4 and IPv6 join states are counted towards the configured join state limit.

The remaining statements are described separately.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 12.2.

sham-link

IN THIS SECTION

- Syntax | 16921
- Hierarchy Level | 16921
- Description | 16921
- Options | 16922
- Required Privilege Level | 16922
- Release Information | 16922

Syntax

```
sham-link {
    local address
    {
        keychain keychain-name;
    }
}
```

Hierarchy Level

```
[edit logical-systems logical-system-name routing-instances routing-instance-name protocols
ospf],
[edit routing-instances routing-instance-name protocols ospf]
```

Description

Configure the local endpoint of a sham link.

You can create an intra-area link or sham link between two provider edge (PE) routing devices so that the VPN backbone is preferred over the back-door link. A back-door link is a backup link that connects customer edge (CE) devices in case the VPN backbone is unavailable. When such a backup link is available and the CE devices are in the same OSPF area, the default behavior is to prefer this backup link over the VPN backbone. This is because the backup link is considered an intra-area link, while the VPN backbone is always considered an inter-area link. Intra-area links are always preferred over inter-area links.

The sham link is an unnumbered point-to-point intra-area link between PE devices. When the VPN backbone has a sham intra-area link, this sham link can be preferred over the backup link if the sham link has a lower OSPF metric than the backup link.

The sham link is advertised using Type 1 link-state advertisements (LSAs). Sham links are valid only for routing instances and OSPFv2.

Each sham link is identified by the combination of a local endpoint address and a remote endpoint address.

Options

`local` *`address`*—The address for the local endpoint of the sham link.

`keychain` *`keychain-name`*—For each keychain, you must specify a name.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration

Release Information

Statement introduced before Junos OS Release 7.4.

The option `keychain` *`keychain-name`* introduced in Junos OS and Junos OS Evolved Release 24.2R1.

[edit routing-instances routing-instance-name protocols ospf area area-id]
```

Description

Configure the remote endpoint of a sham link.

You can create an intra-area link or sham link between two provider edge (PE) routing devices so that the VPN backbone is preferred over the back-door link. A back-door link is a backup link that connects customer edge (CE) devices in case the VPN backbone is unavailable. When such a backup link is available and the CE devices are in the same OSPF area, the default behavior is to prefer this backup link over the VPN backbone. This is ecause the backup link is considered an intra-area link, while the VPN

backbone is always considered an inter-area link. Intra-area links are always preferred over inter-area links.

The sham link is an unnumbered point-to-point intra-area link between PE devices. When the VPN backbone has a sham intra-area link, this sham link can be preferred over the backup link if the sham link has a lower OSPF metric than the backup link.

The sham link is advertised using Type 1 link-state advertisements (LSAs). Sham links are valid only for routing instances and OSPFv2.

Each sham link is identified by the combination of a local endpoint address and a remote endpoint address.

Options

address	Address for the remote end point of the sham link.
demand-circuit	Configure an interface as a demand circuit.
ipsec-sa ***name***	Apply the named IPsec authentication to the OSPF interface or virtual link or to an OSPFv2 remote sham link.
metric ***metric***	Specify the cost of an OSPF interface. The cost is a routing metric that is used in the link-state calculation. To set the cost of routes exported into OSPF, configure the appropriate routing policy. Range is 1 through 65,535. By default, the cost of an OSPF route is calculated by dividing the reference-bandwidth value by the bandwidth of the physical interface. Any specific value you configure for the metric overrides the default behavior of using the reference-bandwidth value to calculate the cost of the route for that interface.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

Support for `ipsec-sa` statement added in Junos OS Release 8.3.

Defining Virtual Path Tunnels

shaping-rate (Traffic Control Profiles)

IN THIS SECTION

- Syntax | 16927
- Hierarchy Level | 16927
- Description | 16927
- Default | 16928
- Options | 16928
- Required Privilege Level | 16928
- Release Information | 16928

Syntax

```
shaping-rate (rate | percent percentage);
```

Hierarchy Level

```
[edit class-of-service traffic-control-profiles profile-name]
```

NOTE: Only devices that support enhanced transmission selection (ETS) or hierarchical scheduling support the `traffic-control-profiles` hierarchy.

Description

Configure the shaping rate. The shaping rate throttles the rate of packet transmission by setting a maximum bandwidth (rate in bits per second) or a maximum percentage of bandwidth for a queue or a forwarding class set. You specify the maximum bandwidth for a queue by using a scheduler map to associate a forwarding class (queue) with a scheduler that has a configured shaping rate.

For ETS or hierarchical scheduling configuration, you specify the maximum bandwidth for a forwarding class set by setting the shaping rate for a traffic control profile. Then you associate the scheduler map with the traffic control profile, and then you apply the traffic control profile and a forwarding class set to an interface.

The shaping rate as an absolute maximum usage and not as additional usage beyond the configured transmit rate (the minimum guaranteed bandwidth for a queue) or the configured guaranteed rate (the minimum guaranteed bandwidth for a forwarding class set).

NOTE: When you set the maximum bandwidth (`shaping-rate` value) for a queue or for a priority group at 100 Kbps or less, the traffic shaping behavior is accurate only within +/– 20 percent of the configured `shaping-rate` value.

NOTE: On QFX5200, QFX5100, and EX4600 devices, we recommend that you always apply a shaping rate to strict-high priority queues to prevent them from starving other queues. If you do not apply a shaping rate to limit the amount of bandwidth a strict-high priority queue can use, then the strict-high priority queue can use all of the available port bandwidth and starve other queues on the port.

NOTE: On QFX5200 Series switches, a granularity of 64kbps is supported for the shaping rate. Therefore, the shaping rate on queues for 100g interfaces might not be applied correctly.

NOTE: QFX10000 Series switches do not support the shaping-rate statement. However, you can configure the transmit-rate `exact` option to prevent a queue from consuming more bandwidth than you want the queue to consume.

On QFX10000 Series switches, we recommend that you use the transmit rate to set a limit on the amount of bandwidth that receives strict-high priority treatment on a strict-high priority queue. Traffic up to the transmit rate receives strict-high priority treatment. Traffic in excess of the transmit rate is treated as best-effort traffic that receives the strict-high priority queue excess rate weight of “1”. Do not use a shaping rate to set a maximum bandwidth limit on strict-high priority queues on QFX10000 Series switches.

Default

If you do not configure a shaping rate, the default shaping rate is 100 percent (all of the available bandwidth), which is the equivalent of no rate shaping.

Options

`percent` *`percentage`*—Shaping rate as a percentage of the available interface bandwidth.

- **Range:** 1 through 100 percent

`rate`—Peak (maximum) rate, in bits per second (bps). You can specify a value in bits per second either as a complete decimal number or as a decimal number followed by the abbreviation k (1000), m (1,000,000), or g (1,000,000,000).

- **Range:** 1000 through 10,000,000,000 bps

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.1.

Syntax

```
shaping-rate rate;
```

Hierarchy Level

```
[edit class-of-service interfaces interface-name],
[edit class-of-service interfaces interface-name unit logical-unit-number]
```

Description

For logical interfaces on which you configure packet scheduling, configure traffic shaping by specifying the amount of bandwidth to be allocated to the logical interface. Applying a shaping rate can help ensure that higher-priority services do not starve lower-priority services.

For physical interfaces, by default, shaping is not configured and traffic can be up to the line rate for that interface. Port shaping enables you to control the amount of traffic passing through a physical interface. Port shaping enables you to shape the aggregate traffic through an interface to a rate that is less than the line rate for that interface. This can be useful to reduce downstream congestion.

NOTE: For platforms that support both logical and physical interface shaping, logical and physical interface traffic shaping rates are mutually exclusive. This means you can include the `shaping-rate` statement at the `[edit class-of-service interfaces interface-name]` hierarchy level or at the `[edit class-of-service interfaces interface-name unit logical-unit-number]` hierarchy level, but not at both.

NOTE: For MX Series routers and for EX Series switches, the shaping rate value for the physical interface at the `[edit class-of-service interfaces interface-name]` hierarchy level must be a minimum of 160 Kbps. If the value is less than the sum of the logical interface guaranteed rates, you cannot apply the shaping rate to a physical interface.

For PTX Series routers, the shaping rate value for the physical interface at the `[edit class-of-service interfaces interface-name]` hierarchy level must be a minimum of 1 Gbps and an incremental granularity of 0.1 percent of the physical interface speed after that (for example, 10 Mbps increments on a 10 Gbps interface).

On EX4650, QFX5110, QFX5120, QFX5200, QFX5210 Series switches, when you configure a shaping rate on an aggregated Ethernet (ae) interface, all members of the ae interface are shaped at the configured shaping rate. For example, consider an interface ae0 that consists of three interfaces: xe-0/0/0, xe-0/0/1, and xe-0/0/2. If you configure a shaping rate of X Mpbs on ae0, traffic up to the rate of X Mpbs flows through each of the three interfaces. Therefore, the total traffic flowing through ae0 can be at the rate of 3X Mbps.

NOTE: Starting in Junos OS Release 24.2R1, we support `shaping-rate` on aggregated Ethernet (AE) interfaces and logical interface of aggregated Ethernet (AE) interfaces on Junos OS PTX Series platforms.

Alternatively, you can configure a shaping rate for a logical interface and oversubscribe the physical interface by including the `shaping-rate` statement at the `[edit class-of-service traffic-control-profiles]`

hierarchy level. With this configuration approach, you can independently control the delay-buffer rate, as described in *Oversubscribing Interface Bandwidth*.

Default

If you do not include this statement at the `[edit class-of-service interfaces interface-name unit logical-unit-number]` hierarchy level, the default logical interface bandwidth is the average of unused bandwidth for the number of logical interfaces that require default bandwidth treatment. If you do not include this statement at the `[edit class-of-service interfaces interface-name]` hierarchy level, the default physical interface bandwidth is the average of unused bandwidth for the number of physical interfaces that require default bandwidth treatment.

Options

rate Peak rate, in bits per second (bps). You can specify a value in bits per second either as a complete decimal number or as a decimal number followed by the abbreviation `k` (1000), `m` (1,000,000), or `g` (1,000,000,000).

- **Range:** 1000 through 6,400,000,000,000 bps.

> **NOTE**: For all MX Series and EX Series interfaces, the rate can be from 65,535 to 6,400,000,000,000 bps.
>
> For all PTX Series interfaces, the rate can be from 1,000,000,000 to 160,000,000,000 bps in increments of 0.1 percent of the interface speed.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

`[edit class-of-service interfaces interface-name]` hierarchy level added in Junos OS Release 7.5.

Syntax

```
shaping-rate rate <overhead bytes> ;
```

Hierarchy Level

```
[edit class-of-service interfaces interface-name],
[edit class-of-service interfaces interface-name unit logical-unit-number]
```

Description

For logical interfaces on which you configure packet scheduling, configure traffic shaping by specifying the amount of bandwidth to be allocated to the logical interface.

Logical and physical interface traffic shaping can be configured together. This means you can include the `shaping-rate` statement at the `[edit class-of-service interfaces interface interface-name]` hierarchy level *and* the `[edit class-of-service interfaces interface interface-name unit logical-unit-number]` hierarchy level. If you configure traffic shaping at both the logical and physical interface levels, the logical interface shaping credit is checked and updated before the physical interface shaping credit.

Alternatively, you can configure a shaping rate for a logical interface and oversubscribe the physical interface by including the `shaping-rate` statement at the `[edit class-of-service traffic-control-profiles]` hierarchy level. With this configuration approach, you can independently control the delay-buffer rate.

On the physical interface, you can set the Layer 2 overhead adjustment to the shaping rate calculation at egress.

Default

If you do not include this statement at the `[edit class-of-service interfaces interface interface-name unit logical-unit-number]` hierarchy level, the default logical interface bandwidth is the average of unused bandwidth for the number of logical interfaces that require default bandwidth treatment. If you do not include this statement at the `[edit class-of-service interfaces interface interface-name]` hierarchy level, the default physical interface bandwidth is the average of unused bandwidth for the number of physical interfaces that require default bandwidth treatment.

Options

rate Peak rate, in bits per second (bps). You can specify a value in bits per second either as a complete decimal number or as a decimal number followed by the abbreviation `k` (1000), `m` (1,000,000), or `g` (1,000,000,000).

- **Range:** 1000 through 6,400,000,000,000 bps

overhead Layer 2 shaping overhead adjustment to be applied at egress (bytes).

Syntax

```
shaping-rate (percent percentage / rate) <burst-size bytes>;
```

Hierarchy Level

```
[edit class-of-service traffic-control-profiles profile-name]
```

Description

FConfigure a shaping rate for a logical interface. On some interfaces, you can also configure an optional burst size for a logical interface. This can help to ensure that higher-priority services do not starve lower-priority services.

For physical interfaces on T4000 router interfaces on Type 5 FPCs and on PTX Series routers, configure traffic shaping rate.

The sum of the shaping rates for all logical interfaces on the physical interface can exceed the physical interface bandwidth. This practice is known as oversubscription of the peak information rate (PIR).

Default

The default behavior depends on various factors. For more information, see *Bandwidth and Delay Buffer Allocations by Configuration Scenario*.

Options

percent *percentage*

Shaping rate as a percentage of the available interface bandwidth.

- **Range:** 1 through 100 percent

rate

Peak shaping rate, in bits per second (bps). You can specify a value in bits per second either as a complete decimal number or as a decimal number followed by the abbreviation `k` (1000), `m` (1,000,000), or `g` (1,000,000,000).

Range:

- 1000 through 6,400,000,000,000 bps
- T4000 routers with Type 5 FPCs—The shaping rate value for the physical interface must be a minimum of 292 Kbps. The maximum value of `shaping-rate` is limited by the maximum transmission rate of the interface.

`burst-size` *bytes*

(Optional) Maximum burst size, in bytes.

- **Range:** 0 through 1,000,000,000

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 7.6.

Option `burst-size` introduced in Junos OS Release 9.4.

> **NOTE**: Option `burst-size` is not supported on MPC5 interfaces. The `burst-size` configuration is allowed on these interfaces, but does not take effect.

Statement introduced for PTX Series Packet Transport Routers in Junos OS Release 16.1. PTX Series Packet Transport Routers do not support the `burst-size` option or defining the `shaping-rate` as a percentage.

shaping-rate-priority-low

IN THIS SECTION

- Syntax | 16952
- Hierarchy Level | 16952
- Description | 16953
- Default | 16953
- Options | 16953
- Required Privilege Level | 16953
- Release Information | 16954

Syntax

```
shaping-rate-priority-low (percent percentage | rate) <burst-size bytes>;
```

Hierarchy Level

```
[edit class-of-service traffic-control-profiles profile-name],
[edit dynamic-profiles profile-name class-of-service traffic-control-profiles profile-name]
```

Description

For MIC and MPC interfaces on MX Series routers, configure a shaping rate and optional burst size for low priority traffic. This can help to make sure higher priority services do not starve lower priority services.

> **NOTE**: Option `burst-size` is not supported on MPC5 interfaces. The `burst-size` configuration is allowed on these interfaces, but does not take effect.

Default

If you do not include this statement, the default shaping rate for this priority is determined by the `shaping-rate` statement in the traffic control profile.

Options

`percent` *percentage*—Specify the shaping rate as a percentage of the overall shaping rate.

- **Range:** 1 through 100

rate—Peak rate, in bits per second (bps). You can specify a value in bits per second either as a complete decimal number or as a decimal number followed by the abbreviation `k` (1000), `m` (1,000,000), or `g` (1,000,000,000).

- **Range:** 1000 through 6,400,000,000,000

> **NOTE**: Through Junos OS Release 13.3, the upper limit is 160,000,000,000 bps. Beginning with Junos OS Release 14.1, the upper limit is 6,400,000,000,000 bps.

- **Default:** None

`burst-size` *bytes*—Maximum burst size, in bytes.

- **Range:** 0 through 1,000,000,000

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 10.1.

`percent` option added in Junos OS Release 19.3R1.

```

Description

For MPC7E-MRATE, MPC7E-10G, MPC8E, and MPC9E interfaces on MX Series routers, configure a shaping rate and optional burst size for strictly high priority traffic. This can help to make sure higher priority services do not starve lower priority services.

Default

If you do not include this statement, the default shaping rate for this priority is determined by the `shaping-rate` statement in the traffic control profile.

Options

`percent` *`percentage`*—Specify the shaping rate as a percentage of the overall shaping rate.

- **Range:** 1 through 100

`rate`—Peak rate, in bits per second (bps). You can specify a value in bits per second either as a complete decimal number or as a decimal number followed by the abbreviation `k` (1000), `m` (1,000,000), or `g` (1,000,000,000).

- **Range:** 1000 through 6,400,000,000,000
- **Default:** None

`burst-size` *`bytes`*—Maximum burst size, in bytes.

- **Range:** 1 through 1,000,000,000

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 16.1.

`percent` option added in Junos OS Release 19.3R1.

shaping-rate (Schedulers)

IN THIS SECTION

- Syntax | 16960
- Hierarchy Level | 16961
- Description | 16961
- Default | 16961
- Options | 16961
- Required Privilege Level | 16962
- Release Information | 16962

Syntax

```
shaping-rate (percent percentage | rate) <burst-size  bytes>;
```

Hierarchy Level

```
[edit class-of-service schedulers scheduler-name]
```

Description

Define a limit on bandwidth usage for a forwarding class/queue.

The `transmit-rate` statement at the `[edit class-of-service schedulers scheduler-name]` hierarchy level configures the minimum bandwidth allocated to a queue. The transmission bandwidth can be configured as an exact value or allowed to exceed the configured rate if additional bandwidth is available from other queues.

Configure the shaping rate as an absolute maximum usage and not the additional usage beyond the configured transmit rate.

Default

If you do not include this statement, the default shaping rate is 100 percent, which is the same as no shaping at all.

Options

percent *percentage*

Shaping rate as a percentage of the available interface bandwidth.

- **Range:** 0 through 100 percent

> **NOTE**: If you configure a shaping rate as a percent in a scheduler, the effective shaping rate is calculated based on the following hierarchy:
>
> 1. Logical interface shaping rate, if configured
> 2. Physical interface shaping rate, if configured
> 3. Physical interface bandwidth

rate

Peak rate, in bits per second (bps). You can specify a value in bits per second either as a complete decimal number or as a decimal number followed by the abbreviation `k` (1000), `m` (1,000,000), or `g` (1,000,000,000).

- **Range:** 3200 through 6,400,000,000,000 bps

burst-size *bytes*

Maximum burst size, in bytes. The burst value determines the number of rate credits that can accrue when the queue or scheduler node is held in the inactive round robin.

- **Range:** 0 through 1,000,000,000

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.

The `burst-size` option added in Junos OS Release 11.4.

shared-bandwidth-policer (Configuring)

IN THIS SECTION

- Syntax | **16963**
- Hierarchy Level | **16963**
- Description | **16963**
- Required Privilege Level | **16963**
- Release Information | **16963**

Syntax

```
shared-bandwidth-policer;
```

Hierarchy Level

```
[edit firewall policer policer-name],
[edit firewall three-color-policer policer-name],
[edit firewall hierarchical-policer policer-name]
```

Description

Policer instances share bandwidth. This enables configuration of interface-specific policers applied on an aggregated Ethernet bundle or an aggregated SONET bundle to match the effective bandwidth and burst-size to user-configured values. This feature is supported on the following platforms: T Series routers, M120, M10i, M7i (CFEB-E only), M320 (SFPC only), MX240, MX480, and MX960 with DPC, MIC, and MPC interfaces and EX Series switches.

NOTE: This statement is not supported on T4000 Type 5 FPCs.

Required Privilege Level

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 11.2.

Support for MX Series MPC and MIC interfaces added in Junos OS Release 12.1.

Policer Support for Aggregated Ethernet Interfaces Overview

shared-buffer

IN THIS SECTION

- Syntax | 16964
- Hierarchy Level | 16964
- Description | 16965
- Options | 16966
- Required Privilege Level | 16966
- Release Information | 16966

Syntax

```
shared-buffer {
    egress {
        buffer-partition (lossless | lossy | multicast) {
            percent percent;
            dynamic-threshold threshold-value;
        }
        percent percent;
    }
    ingress {
        percent percent;
        buffer-partition (lossless | lossless-headroom | lossy) {
            percent percent;
            dynamic-threshold threshold-value;
        }
    }
}
```

Hierarchy Level

```
[edit class-of-service]
```

Description

Configure the global shared buffer pool allocation to ports. Shared buffers are a pool of buffer space that the system can allocate dynamically across all of its ports as memory space is needed. Some buffer space is reserved for dedicated buffers (buffers allocated permanently to ports), headroom buffers (buffers that help prevent packet loss on lossless flows), and other buffers.

The device uses the shared-buffer pool to absorb traffic bursts after the dedicated-buffer-pool is exhausted. The shared pool threshold is dynamically calculated based on a factor called "*alpha*".

Configure the way the system uses the available (user-configurable) buffer space by setting the `shared-buffer` percentage for the ingress buffer pool and for the egress buffer pool.

The percentage you specify is the percentage of available buffer space allocated to the global shared ingress buffer pool or to the global shared egress buffer pool. If you allocate less than 100 percent of the available buffer space to the shared buffer pool, the remaining buffer space is added to the dedicated buffer pool. (You cannot directly configure the dedicated buffer pool for each port; dedicated buffers are allocated evenly across all the ports.)

You can adjust the maximum size of the shared-buffer pool by configuring the dynamic-threshold values:

- By adjusting the value for the egress partition (the calculation includes the alpha value and the number of competing queues).

```
[edit class-of-service shared-buffer egress buffer-partition dynamic-threshold threshold-value]
```

- By adjusting the value for the ingress partition (the calculation includes the alpha value and the number of competing queues).

```
[edit class-of-service shared-buffer ingress buffer-partition dynamic-threshold threshold-value
```

CAUTION: Changing the buffer configuration is a disruptive event. Traffic stops on *all* ports until the buffer reprogramming is complete.

You can also partition the ingress shared buffer pool and the egress shared buffer pool to adjust the buffer allocations for different mixes of network traffic (best-effort, lossless, multicast) using the `buffer-partition` statement.

NOTE: If you commit a buffer configuration for which the device does not have sufficient resources, the device might log an error instead of returning a commit error. In that case, a syslog message is displayed on the console. For example:

```
user@host# commit
configuration check succeeds

Message from syslogd@host at Jun 13 11:11:10  ...
host dc-pfe: Not enough Ingress Lossless headroom.(Already allocated more).
Dedicated : 14340 Lossy : 47100 Lossless 4239 Headroom 21195 Avail : 20781
commit complete
```

If the buffer configuration commits but you receive a syslog message that indicates the configuration cannot be implemented, you can:

- Reconfigure the buffers or reconfigure other parameters (for example, the PFC configuration, which affects the need for lossless headroom buffers and lossless buffers—the more priorities you pause, the more lossless and lossless headroom buffer space you need), then attempt the commit operation again.
- Roll back the device to the last successful configuration.

If you receive a syslog message that says the buffer configuration cannot be implemented, you must take corrective action. If you do not fix the configuration or roll back to a previous successful configuration, the system behavior is unpredictable.

shmlog (Shared Memory Log)

IN THIS SECTION

Syntax | 16979

- Hierarchy Level | 16979
- Description | 16979
- Options | 16980
- Required Privilege Level | 16981
- Release Information | 16981

Syntax

```
shmlog {
    disable;
    file filename <files maximum-no-files> <size maximum-file-size>;
    filtering enable;
    log-name {
        all;
        logname {
            <brief | detail | extensive | none | terse>;
            <file-logging |no-file-logging>;
        }
        }
    log-type (debug | info | notice);
|
```

Hierarchy Level

```
[edit system services subscriber-management overrides]
```

Description

Junos OS uses a shared memory space to store log entries for subscriber service daemons including jpppd, jdhcpd, jl2tpd, autoconfd, bbe-smgd, authd, cosd, and dfwd. Shared memory logging is enabled by default and occurs at the client level. You can view the shmlogs on a per subscriber basis, or use filters to retrieve logs according to a variety of different parameters such as interface name, IP address, session

ID, subnet, and VLAN in addition to the Client Identifier or Client DUID. Filtering is disabled by default. To see a complete list of supported filters, use this command:

```
user@rdevice> show shmlog entries logname all ?
```

When viewing logs you can limit results on the basis of event flags that include interface events, routing process interaction events, l2tp tunneling events, and ldap authentication events. To see a complete list of supported flags, use this command:

```
user@rdevice> show shmlog entries logname all flag-name ?
```

NOTE: Some platforms other than MX Series routers use shared memory logs for internal processes. These logs are not intended for customer use.

Options

disable Name of the command to override the default behavior. Use this option to disable shared memory logging; it is always enabled otherwise.

file Name of the file containing the shmlogs. Use this option to redirect shmlogs to a file for file-based logging. Specify the file name, define the number of files (from 2 to 1000), and set the maximum file size (from 10240 to 1073741824 bytes). Data will be written to the **/var/log/shmlog/** directory. Files follow this naming convention: **<cfg-file-name>-<daemon>-<severity>.log**. The shmlog files are not human-readable, so to access the logs you must first run the following command to generate a file in the **/var/log/<file-name>/** directory with logs from all daemons:

```
user@rdevice> show shmlog entries filename /var/log/shmlog/<file-name>* logname all
```

If you then want to view logs from a specific daemon, you need to run the following command to generate a file under the **/var/log/<file-name>/** directory with complete logs:

```
user@rdevice> show shmlog entries filename /var/log/shmlog/<filename>  logname authd*
```

filtering Command to enable filtering. Filtering is subscriber centric and is useful for debugging and troubleshooting. It is disabled by default so you must use this option to enable it.

For example, if you want to quickly view the transmit packet logs for subscribers with interface-name pp0.100, you could use the following command to display only the relevant results:

```
user@rdevice> show shmlog entries logname jpppd* interface-name pp0.100 flag transmit-
packets
```

To debug sessions according to the interface name, use this command:

```
user@rdevice> show shmlog entries logname all interface-name pp0.100
```

To debug sessions that are logging in via VLAN 7 on physical-interface ge-0/0/0, use this command:

```
user@rdevice> show shmlog entries logname all vlan 7 physical-interface ge-0/0/0
```

log-name Name of the file containing the log output. Use this option to override all logs or a specified log, and to set the verbosity level (brief, detail, extensive, none, or terse). For example, to configure **bbe-autoconf-info** for detailed file logging, you would use the following command:

```
user@rdevice> [edit system services subscriber-management overrides shmlog]
user@rdevice> set log-name bbe-autoconf-info detail file-logging
```

log-type Severity level of the collected logs. Use this option to configure the severity level for captured logs (notice, info, or debug).

```

Description

Enable DHCP short-cycle protection to reduce resource usage associated with connection and authentication processing in highly scaled networks. You must configure both the minimum duration and the maximum duration for the lockout period.

The router detects short-lived client sessions and clients that repeatedly fail session negotiation, then locks them out from access by dropping subsequent DHCP discover or solicit messages from the client. The clients are tracked by the client identifier (client key), which can be a MAC address or some other unique value for DHCPv4 clients or the DUID for DHCPv6 clients. Locked-out clients are entered in the lockout database. If a locked-out client attempts another session before the grace time threshold is reached, it is locked out again. Each successive lockout period is increased exponentially up to the maximum lockout period. The grace time threshold is automatically set at whichever value is larger, 900 seconds or the configured maximum value.

Options

lockout-max-time *seconds*

Maximum length of any lockout period; the upper bound of the lockout range.

- **Range:** 1 through 86400

lockout-min-time *seconds*

Minimum length of any lockout period; the lower bound of the lockout period. The minimum value is the length of the first lockout period for a client. It cannot be greater than the maximum value. If you set it to the same value as the maximum, then the lockout period is fixed and does not increase for a client's subsequent lockouts.

- **Range:** 1 through 86400

```

Description

Configure the router to temporarily prevent (lock out) a failed or short-lived (also known as short-cycle) PPPoE subscriber session from reconnecting for a default or configurable period of time. You can optionally override the default lockout time, 1 through 300 seconds (5 minutes), by specifying the minimum lockout time and maximum lockout time as part of the `short-cycle-protection` statement. You can optionally specify the lockout based on the ACI, which locks out all PPPoE subscriber sessions that come from the same household and share the same ACI string.

You can configure PPPoE subscriber session lockout, also known as short-cycle protection, for VLAN, VLAN demux, and PPPoE-over-ATM dynamic subscriber interfaces. Enabling PPPoE subscriber session lockout reduces excessive loading on the router, prevents failed or short-lived sessions from disrupting other sessions on the same underlying interface, and preserves valuable system resources.

Options

`filter aci`—(Optional) Use the agent circuit identifier (ACI) lockout for all subscriber sessions.

`lockout-time-min` *`minimum-seconds`*—(Optional) Use the specified minimum lockout time for failed or short-lived PPPoE subscriber sessions. The *minimum-seconds* value must be less than or equal to the *maximum-seconds* value. Setting *minimum-seconds* and *maximum-seconds* to the same value causes the lockout time to become fixed at that value.

- **Range:** 1 through 86400 (24 hours)
- **Default:** 1

`lockout-time-max` *`maximum-seconds`*—(Optional) Use the specified maximum lockout time for failed or short-lived PPPoE subscriber sessions. The *maximum-seconds* value must be equal to or greater than the *minimum-seconds* value. Setting *maximum-seconds* and *minimum-seconds* to the same value causes the lockout time to become fixed at that value.

- **Range:** 1 through 86400 (24 hours)
- **Default:** 300 (5 minutes)

should-secure

IN THIS SECTION

- Syntax | 16993
- Hierarchy Level | 16993
- Description | 16993
- Default | 16993
- Required Privilege Level | 16993
- Release Information | 16994

Syntax

```
should-secure;
```

Hierarchy Level

```
[edit security macsec connectivity-association connectivity-association-name mka]
```

Description

Configure the `should-secure` statement to enable fail open mode for Media Access Control Security (MACsec). Fail open mode ensures that traffic continues to flow if the MACsec Key Agreement (MKA) session is not established.

When `should-secure` is configured:

- If the MKA session is not established, traffic is still allowed in clear text without the MACsec header.
- If the MKA session is established successfully, traffic is allowed with MACsec headers.

Fail open mode is recommended for service providers that prioritize network availability. Before you enable fail open mode, consider the sensitivity of the traffic you are attempting to secure with MACsec.

> **NOTE**: Setting or unsetting this configuration statement will cause the tunnel to be re-established.

Default

Fail open mode is not enabled by default. You must configure `should-secure` to enable this feature. When `should-secure` is not configured:

- If the MKA session is not established, all traffic is discarded except Extensible Authentication Protocol over LAN (EAPoL) packets.
- If the MKA session is established, traffic is transmitted with MACsec headers.

Required Privilege Level

admin—To view this statement in the configuration.

admin-control—To add this statement to the configuration.

Release Information

Statement introduced in Junos OS Release 17.4.

show access-security router-advertisement state

IN THIS SECTION

- Syntax | **16998**
- Description | **16999**
- Options | **16999**
- Required Privilege Level | **16999**
- Output Fields | **16999**
- Sample Output | **17000**
- Release Information | **17000**

Syntax

```
show access-security router-advertisement state
<interface interface-name>
```

Description

Display the IPv6 Router Advertisement (RA) guard state information. Stateful RA guard enables the switch to learn about the sources of RA messages for a certain period of time. When the learning period ends, the switch has a record of which interfaces are attached to links with valid IPv6 routers. If there is no valid IPv6 router attached to the interface, the switch dynamically transitions the interface from the learning state into the blocking state. Subsequent RA messages received after the transition to blocking state are dropped. If there is a valid IPv6 router attached to the interface, the interface transitions to the forwarding state, and subsequent RA messages that can be validated against the configured policy are forwarded.

Options

interface *interface-name* (Optional) Display the RA guard entries for the specified interface.

Required Privilege Level

view

Output Fields

Table 143 on page 16999 lists the output fields for the `show access-security router-advertisement state` command. Output fields are listed in the approximate order in which they appear.

Table 143: show access-security router-advertisement state Output Fields

Field Name	Field Description
`Interface`	Displays the interface on which stateful IPv6 RA guard is enabled.

Table 143: show access-security router-advertisement state Output Fields *(Continued)*

Field Name	Field Description
State	Displays one of the following states: • OFF—The interface operates as if RA guard is not available. • BLOCKED—The interface blocks ingress RA messages. • FORWARDING—The interface forwards ingress RA messages that can be validated against the configured policy. • LEARNING—The switch is actively acquiring information about the IPv6 routing device connected to the interface. • TRUSTED—The interface forwards all ingress RA messages without performing policy checks.

Sample Output

show access-security router-advertisement state

```
user@device> show access-security router-advertisement state
Interface        state
ge-0/0/0.0     LEARNING
ge-1/0/0.0     FORWARDING
ge-1/0/0.0     BLOCKED
```

Syntax

```
show access-security slaac-snooping binding
<interface (interface-name | all>
<vlan vlan-name>
<vlan vlan-name routing-instance routing-instance-name>
<vlan vlan-name logical-system logical-system-name>
```

Description

Display the snooping table entries for IPv6 clients using stateless address auto-configuration (SLAAC). SLAAC snooping extracts address information from Duplicate Address Detection (DAD) packets exchanged during the SLAAC process to build the SLAAC snooping table. The IPv6-MAC address bindings in this table are used to inspect and validate NDP/IP packets sent by IPv6 clients using SLAAC.

Options

`interface (interface-name | all)`	Display the SLAAC snooping entries for the specified interface or for all interfaces.
`vlan vlan-name`	Display the SLAAC snooping entries for the specified VLAN.
`logical-system logical-system-name`	Display the SLAAC snooping entries for the specified logical system.

routing-instance *routing-instance-name*	Display the SLAAC snooping entries for the specified routing instance.

Required Privilege Level

view

Output Fields

Table 145 on page 17004 lists the output fields for the `show access-security slaac-snooping binding` command. Output fields are listed in the approximate order in which they appear.

Table 145: show access-security slaac-snooping binding Output Fields

Field Name	Field Description
`IPv6 address`	IPv6 address of the network device; bound to the MAC address.
`MAC address`	MAC address of the network device; bound to the IPv6 address.
`Vlan`	VLAN name of the network device whose MAC address is shown.
`Expires`	Length of time remaining until the address binding entry expires.
`State`	State of the address binding: • `INIT` • `WAIT` • `BOUND` • `RENEWING` • `AUTO DAD`
`Interface`	Interface address (port).

Sample Output

show access-security slaac-snooping binding

```
user@device> show access-security slaac-snooping binding

show access-security slaac-snooping state

IN THIS SECTION

- Syntax | 17006
- Description | 17006
- Options | 17006
- Required Privilege Level | 17006
- Output Fields | 17006
- Sample Output | 17007
- Release Information | 17007

Syntax

```
show access-security slaac-snooping state
<interface interface-name I all>
```

Description

Display the SLAAC snooping state information to show interfaces that are blocked. SLAAC snooping extracts address information from Duplicate Address Detection (DAD) packets exchanged during the SLAAC process to build the SLAAC snooping table. The IPv6-MAC address bindings in this table are used to inspect and validate NDP/IP packets sent by IPv6 clients using SLAAC.

To restore an interface that has been blocked, you must issue the `request access-security slaac-snooping unblock` command.

Options

interface (*interface-name* | all)	Display the SLAAC snooping state for the specified interface.

Required Privilege Level

view

Output Fields

Table 146 on page 17006 lists the output fields for the `show access-security slaac-snooping state` command. Output fields are listed in the approximate order in which they appear.

Table 146: show access-security slaac-snooping state Output Fields

Field Name	Field Description
`Interface`	Displays the interface on which SLAAC snooping is enabled.
`State`	Shows that the interface is blocked, meaning incoming DAD and ND requests on the interface will be dropped.

Sample Output

show access-security slaac-snooping state

```
user@device> show access-security slaac-snooping state
Interface         State
ge-0/0/40.0     BLOCKED
```

Release Information

Command introduced in Junos OS Release 19.2R1.

show access-security slaac-snooping statistics

IN THIS SECTION

- Syntax | 17008
- Description | 17008
- Options | 17008
- Required Privilege Level | 17008
- Output Fields | 17008
- Sample Output | 17010
- Release Information | 17010

Syntax

```
show access-security slaac-snooping statistics
<interface (interface-name | all>
```

Description

Display the statistics for IPv6 clients using stateless address auto-configuration (SLAAC). SLAAC snooping extracts address information from Duplicate Address Detection (DAD) packets exchanged during the SLAAC process to build the SLAAC snooping table. The IPv6-MAC address bindings in this table are used to inspect and validate NDP/IP packets sent by IPv6 clients using SLAAC.

Options

interface (*interface-name* | all)	Display the SLAAC snooping statistics for the specified interface or for all interfaces.
logical-system *logical-system-name*	Display the SLAAC snooping statistics for the specified logical system.
routing-instance *routing-instance-name*	Display the SLAAC snooping statistics for the specified routing instance.

Output Fields

Table 147 on page 17009 lists the output fields for the `show access-security slaac-snooping statistics` command. Output fields are listed in the approximate order in which they appear.

Table 147: show access-security slaac-snooping statistics Output Fields

Field Name	Field Description
`Statistics`	Statistics for SLAAC snooping. • `DAD request queued`—Number of Duplicate Address Detection (DAD) requests queued. • `Confirmed bindings`—Number of SLAAC snooping address bindings in confirmed state. • `Decline bindings`—Number of SLAAC snooping address bindings declined. • `Conflicting DAD entries`—Number of address conflicts found by DAD. • `NS request queued`—Number of Neighbor Solicitation requests queued. • `AUTO DAD packet tx`—Number of auto-DAD packets transmitted.
`Packets dropped`	Number of packets not considered for SLAAC snooping because of errors. • `Total`—Total number of packets discarded by SLAAC snooping. • `Bad read`—Number of packets discarded because they could not be read. • `No configuration`—Number of packets discarded because they did not have a valid configuration. • `No VLAN`—Number of packets discarded because they did not belong to a valid VLAN. • `No interface`—Number of packets discarded because they did not belong to a valid interface. • `Request rx on trusted port`—Number of packets discarded because a Request message was received on a trusted port.
`Interface statistics (interface detail)`	Statistics for the specified interface. • `Interface name`—Name of the interface. • `NA-PKT-RX`—Number of Neighbor Advertisement requests received. • `NA-PKT-TX`—Number of Neighbor Advertisement requests transmitted.

Sample Output

show access-security slaac-snooping statistics

```
user@device> show access-security slaac-snooping statistics
Statistics:
---------------
DAD request queued                      4
Confirmed bindings                      4
Decline bindings                        0
Conflicting DAD entries                 0
NS request queued                       2
AUTO DAD packet tx                      2

Packets dropped:
---------------
Total                                   4
Bad Read                                0
No configuration                        0
No VLAN                                 0
No interface                            0
Request rx on Trusted port              0
```

show access-security slaac-snooping statistics interface ge-0/0/40

```
user@device> show access-security slaac-snooping statistics interface ge-0/0/40
    Interface Statistics:
    ---------------------
    Interface Name             NA-PKT-RX          NA-PKT-TX
    ge-0/0/35.0                0                  0

Output Fields

Table 148 on page 17012 lists the output fields for the `show accounting pending-accounting-stops` command. Output fields are listed in the approximate order in which they appear.

Table 148: show accounting pending-accounting-stops Output Fields

Field Name	Field Description	Level of Output
`Type`	Type of client.	All levels
`Username`	Name of the user logged in to the session.	All levels
`Logical system/Routing instance`	Logical system and routing instance used for the session.	`detail` none
`Access-profile`	Access profile used for AAA services for the session.	`detail` none
`Session ID`	ID of the subscriber session; generated when the subscriber logs in. In the `Service name` block, this is the ID of the service session.	All levels
`Accounting Session ID`	ID of the accounting session (RADIUS attribute 44). The ID appears in decimal or description format, as specified by the `accounting-session-id-format` statement.	`detail` none
`IP Address`	IP address of the subscriber.	`detail` none
`IPv6 Prefix`	IPv6 address of the subscriber.	`detail` none

Table 148: show accounting pending-accounting-stops Output Fields *(Continued)*

Field Name	Field Description	Level of Output
`Authentication State`	State of the subscriber authentication session: `AuthInit`, `AuthStart`, `AuthChallenge`, `AuthRedirect`, `AuthClntRespWait`, `AuthAcctVolStatsAckWait`, `AuthAcctStopAckWait`, `AuthServCreateRespWait`, `AuthLogoutStart`, `AuthStateActive`, `AuthClntLogoutRespWait`, `AuthProfileUpdateWait`, `AuthProvisionRespWait`, `AuthProvisionServiceCreationWait`	`detail` none
`Accounting State`	State of the subscriber accounting session: `Acc-Init`, `Acc-Start-Sent`, `Imm-Update-Stats-Pending`, `Acc-Interim-Sent`, `Acc-Stop-Stats-Pending`, `Acc-Stop-Sent`, `Acc-Stop-On-Fail-Deny-Sent`, `Acc-Stop-Ackd`	`detail` none
`Service name`	Name of the attached service or policy.	`detail` none
`Service State`	State of the service provided in the subscriber session.	`detail` none
`Session uptime`	How long the session has been up, in *HH:MM:SS*.	`detail` none
`Accounting status`	Status of the accounting configuration for the service, `on` or `off`, and the type of accounting, `time` or `volume+time`. Configured in RADIUS Service-Statistics VSA [26-69].	`detail` none
`Service accounting session ID`	ID of the service accounting session; RADIUS Acct-Session-Id attribute (44). The ID appears in decimal or description format, as specified by the `accounting-session-id-format` statement.	`detail` none
`Service accounting state`	State of the service accounting session: `Acc-Init`, `Acc-Start-Sent`, `Imm-Update-Stats-Pending`, `Acc-Interim-Sent`, `Acc-Stop-Stats-Pending`, `Acc-Stop-Sent`, `Acc-Stop-On-Fail-Deny-Sent`, `Acc-Stop-Ackd`	`detail` none

Table 148: show accounting pending-accounting-stops Output Fields *(Continued)*

Field Name	Field Description	Level of Output
`Accounting interim interval`	Amount of time between interim accounting updates for this service, in seconds; RADIUS Service-Interim-Acct-Interval VSA [26-140] or Diameter Acct-Interim-Interval AVP (85).	`detail` none
`Subscriber ID`	ID of the subscriber; generated when the subscriber logs in.	`detail` none
`Service ID`	ID of the subscriber service.	All levels
`Service`	Name of the attached service or policy.	`terse`

Output Fields

Table 149 on page 17017 lists the output fields for the `show accounting profile` command. Output fields are listed in the approximate order in which they appear.

Table 149: show accounting profile Output Fields

Field Name	Field Description
Profile	Name of the accounting profile.
Sampling interval	Configured interval, in minutes, for statistic collection.
Profile Usage Count	Number of items configured for collecting accounting statistics.
file information	Information about the accounting profile log, including: • **File**—Name of accounting profile log. If no name is explicitly provided, the name of the accounting profile is used. All statistics files are placed in the **/var/log** directory. • **maximum size**—Configured size. When the size is exceeded, the log file closes and a new log file opens. • **maximum number**—Configured maximum number of log files. • **bytes written**—Number of bytes written to the log file.
Transfer Interval	Length of time (in minutes) the file remains open, receiving statistics before it is closed, transferred, and rotated. When either the time or the file size is exceeded, the file is closed and a new one opened, whether or not a transfer site is specified.

Table 149: show accounting profile Output Fields *(Continued)*

Field Name	Field Description
Next Scheduled Transfer	Time at which the next transfer occurs.

Table 149: show accounting profile Output Fields *(Continued)*

Field Name	Field Description
Column Labels	Names of sampled statistics. This list varies depending on the configuration: • **profile-layout**—List of data fields reported, in the order they appear in the output. • **epoch-timestamp**—Number of seconds since the epoch. • **interfaces**—(For interface, filter, and destination class profiles) Name of the interfaces on which the filter is applied. • **filter-name**—(For filter profiles) Name of the filter. • **counter-name**—(For filter profiles) Name of the counter. • **packet-count**—(For filter and destination class profiles) Number of packets for the counter. • **byte-count**—(For filter and destination class profiles) Number of bytes for the counter. • **input-bytes**—(For interface profiles) Input bytes. • **input-errors**—(For interface profiles) Generic input error packets. • **input-multicast**—(For interface profiles) Input packets arriving by multicast. • **input-packets**—(For interface profiles) Input packets. • **input-unicast**—(For interface profiles) Input unicast packets. • **output-bytes**—(For interface profiles) Output bytes. • **output-errors**—(For interface profiles) Generic output error packets. • **output-multicast**—(For interface profiles) Output packets sent by multicast. • **output-packets**—(For interface profiles) Output packets. • **output-unicast**—(For interface profiles) Output unicast packets. • **no-proto**—(For interface profiles) Packets for unsupported protocol. • **snmp-index**—(For interface profiles) SNMP index. • **destination-class-name**—(For destination class profiles) Configured destination class name.

Table 149: show accounting profile Output Fields *(Continued)*

Field Name	Field Description
	• **host name**—(For Routing Engine profiles) Hostname for the router. • **date-*yyyymmdd***—(For Routing Engine profiles) Date. • **timeofday-*hhmmss***—(For Routing Engine profiles) Time of day. • **uptime**—(For Routing Engine profiles) Time since the last reboot, in seconds. • **cpu1min**—(For Routing Engine profiles) Average system load over the last 1 minute. • **cpu5min**—(For Routing Engine profiles) Average system load over the last 5 minutes. • **cpu15min**—(For Routing Engine profiles) Average system load over the last 15 minutes.
Interface name	Name of the interface configured for this accounting profile.
Filter name	Name of the filter configured for this accounting profile.
routing-engine-stats	Routing Engine accounting profile.
Next Scheduled Collection	Time for next collection of statistics for the named interface.

Output Fields

Table 150 on page 17025 lists the output fields for the `show agent sensors` command. Output fields are listed in the approximate order in which they appear.

Table 150: show agent sensors Output Fields

Field Name	Field Description
`Sensor Information`	Information about sensors configured to monitor system resources and stream data.
`Name`	Name of configured sensor. **NOTE**: Junos OS Evolved Release 19.1R1 and later does not show output for generated child sensors.
`Resource`	Resource string used to configure and identify the system resource enabled to monitor and stream data.
`Sensor-id`	Numerical identifier of the sensor.
`Server Information`	Information about servers configured to collect sensor data.

Table 150: show agent sensors Output Fields *(Continued)*

Field Name	Field Description
`Name`	Name of server.
`Scope-id`	Numerical identifier of a scope.
`Remote-Address`	Destination IP address for exported packets.
`Remote-port`	Destination port for exported packets.
`Profile information`	Information about export profiles for sensors.
`Name`	Name of export profile.
`Rep-interval`	Interval, in seconds, at which the sensor generates data to export.
`Address`	Source address of exported packets.
`Port`	Source port of exported packets.
`Format`	Format of exported data message: `GPB`
`DSCP`	Configured DSCP value for exported packets. **NOTE**: The default value is 0. This value is displayed if you do not configure a DSCP value. **NOTE**: This field is not included with gRPC-based streaming.
`Forwarding-class`	Configured forwarding class for exported packets. **NOTE**: The default value is 0. This value is displayed if you do not configure a forwarding class. **NOTE**: This field is not included with gRPC-based streaming.

Table 150: show agent sensors Output Fields *(Continued)*

Field Name	Field Description
Loss-Priority	Configured loss priority for packets streamed through UDP (MX Series only): high, low, medium-high, medium-low **NOTE**: This field is not included with gRPC-based streaming.

Sample Output

show agent sensors (DDOS sensor)

```
user@host> show agent sensors
Sensor Information Sensor name     :__default_fabric_sensor__

show amt statistics

IN THIS SECTION

- Syntax | 17033
- Description | 17033
- Options | 17033
- Required Privilege Level | 17034
- Output Fields | 17034
- Sample Output | 17036
- Release Information | 17036

Syntax

```
show amt statistics
<instance instance-name>
<logical-system (all | logical-system-name)>
```

Description

Display information about the Automatic Multicast Tunneling (AMT) protocol tunnel statistics.

Options

none	Display summary information about all AMT Protocol tunnels.
instance *instance-name*	(Optional) Display information for the specified instance only.

logical-system (all | *logical-system-name*)	(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields

Table 151 on page 17034 describes the output fields for the `show amt statistics` command. Output fields are listed in the approximate order in which they appear.

Table 151: show amt statistics Output Fields

Field Name	Field Description
AMT receive message count	Summary of AMT statistics for messages received on all interfaces. • **AMT relay discovery**—Number of AMT relay discovery messages received. • **AMT membership request**—Number of AMT membership request messages received. • **AMT membership update**—Number of AMT membership update messages received.
AMT send message count	Summary of AMT statistics for messages sent on all interfaces. • **AMT relay advertisement**—Number of AMT relay advertisement messages sent. • **AMT membership query**—Number of AMT membership query messages sent.

Table 151: show amt statistics Output Fields *(Continued)*

Field Name	Field Description
AMT error message count	Summary of AMT statistics for error messages received on all interfaces. • **AMT incomplete packet**—Number of messages received with length errors so severe that further classification could not occur. • **AMT invalid mac**—Number of messages received with an invalid message authentication code (MAC). • **AMT unexpected type**—Number of messages received with an unknown message type specified. • **AMT invalid relay discovery address**—Number of AMT relay discovery messages received with an address other than the configured anycast address. • **AMT invalid membership request address**—Number of AMT membership request messages received with an address other than the configured AMT local address. • **AMT invalid membership update address**—Number of AMT membership update messages received with an address other than the configured AMT local address. • **AMT incomplete relay discovery messages**—Number of AMT relay discovery messages received that are not fully formed. • **AMT incomplete membership request messages**—Number of AMT membership request messages received that are not fully formed. • **AMT incomplete membership update messages**—Number of AMT membership update messages received that are not fully formed. • **AMT no active gateway**—Number of AMT membership update messages received for a tunnel that does not exist for the gateway that sent the message. • **AMT invalid inner header checksum**—Number of AMT membership update messages received with an invalid IP checksum. • **AMT gateways timed out**—Number of gateways that timed out because of inactivity.

Sample Output

show amt statistics

```
user@host> show amt statistics

AMT receive message count
AMT relay advertisement                      :           2
AMT membership request                       :           5
AMT membership update                        :           5

AMT send message count
AMT relay advertisement                      :           2
AMT membership query                         :           5

AMT error message count
AMT incomplete packet                        :           0
AMT invalid mac                              :           0
AMT unexpected type                          :           0
AMT invalid relay discovery address          :           0
AMT invalid membership request address       :           0
AMT invalid membership update address        :           0
AMT incomplete relay discovery messages      :           0
AMT incomplete membership request messages   :           0
AMT incomplete membership update messages    :           0
AMT no active gateway                        :           0
AMT invalid inner header checksum            :           0
AMT gateways timed out                       :           0
```

Release Information

Command introduced in JUNOS Release 10.2.

Output Fields

Table 152 on page 17038 describes the output fields for the `show amt summary` command. Output fields are listed in the approximate order in which they appear.

Table 152: show amt summary Output Fields

Field Name	Field Description	Level of Output
AMT anycast prefix	Prefix advertised by unicast routing protocols to route AMT discovery messages to the router from nearby AMT gateways.	All levels
AMT anycast address	Anycast address configured from which the anycast prefix is derived.	All levels
AMT local address	Local unique AMT relay IP address configured. Used to send AMT relay advertisement messages, it is the IP source address of AMT control messages and the source address of the data tunnel encapsulation.	All levels
AMT tunnel limit	Maximum number of AMT tunnels that can be created.	All levels
active tunnels	Number of active AMT tunnel interfaces.	All levels

Sample Output

show amt summary

```
user@host> show amt summary
 AMT anycast prefix : 20.0.0.4/32
 AMT anycast address : 20.0.0.4
 AMT local address : 20.0.0.4
 AMT tunnel limit : 1000, active tunnels : 2
```

```
show amt tunnel
<brief | detail>
<gateway-address gateway-ip-address> <port port-number>
<instance instance-name>
<logical-system (all | logical-system-name)>
<tunnel-interface interface-name>
```

Description

Display information about the Automatic Multicast Tunneling (AMT) dynamic tunnels.

Options

none	Display summary information about all AMT protocol instances.
brief | detail	(Optional) Display the specified level of detail.
gateway-address ***gateway-ip-address*** **port** ***port-number***	(Optional) Display information for the specified AMT gateway only. If no port is specified, display information for all AMT gateways with the given IP address.
instance ***instance-name***	(Optional) Display information for the specified instance only.
logical-system (all | ***logical-system-name*****)**	(Optional) Perform this operation on all logical systems or on a particular logical system.
tunnel-interface ***interface-name***	(Optional) Display information for the specified AMT tunnel interface only.

Output Fields

Table 153 on page 17040 describes the output fields for the `show amt tunnel` command. Output fields are listed in the approximate order in which they appear.

Table 153: show amt tunnel Output Fields

Field Name	Field Description	Level of Output
AMT gateway address	Address of the AMT gateway that is being connected by the AMT tunnel.	All levels
port	Client port used by the AMT tunnel.	All levels
AMT tunnel interface	Dynamically created AMT logical interfaces used by the AMT tunnel in the format **ud-FPC/PIC/Port.unit**.	All levels

Table 153: show amt tunnel Output Fields *(Continued)*

Field Name	Field Description	Level of Output
AMT tunnel state	State of the AMT tunnel. The state is normally **Active**. • **Active**—The tunnel is active. • **Pending**—The tunnel creation is pending. This is a transient state. • **Down**—The tunnel is in the down state. • **Graceful restart pending**—Graceful restart is in progress. • **Reviving**—The routing protocol daemon or Routing Engine was restarted (not gracefully). The tunnel remains in the reviving state until the AMT gateway sends a control message. When the message is received the tunnel is moved to the **Active** state. If no message is received before the AMT tunnel inactivity timer expires, the tunnel is deleted.	All levels
AMT tunnel inactivity timeout	Number of seconds since the most recent control message was received from an AMT gateway. If no message is received before the AMT tunnel inactivity timer expires, the tunnel is deleted.	All levels
Number of groups	Number of multicast groups using the tunnel.	All levels
Group	Multicast group address or addresses using the tunnel.	**detail**
Include Source	Multicast source address for each IGMPv3 group using the tunnel.	**detail**
AMT message count	Statistics for AMT messages: • **AMT Request**—Number of AMT relay tunnel request messages received. • **AMT membership update**—Number of AMT membership update messages received.	All levels

Sample Output

show amt tunnel

```
user@host> show amt tunnel
AMT gateway address : 11.11.11.2, port : 2268
 AMT tunnel interface : ud-5/1/10.1120256
 AMT tunnel state : Active
 AMT tunnel inactivity timeout : 15
 Number of groups : 1

AMT message count:
AMT Request    AMT membership update
2              2
```

show amt tunnel detail

```
user@host> show amt tunnel detail
AMT gateway address : 11.11.11.2, port : 2268
 AMT tunnel interface : ud-5/3/10.1120512
 AMT tunnel state : Active
 AMT tunnel inactivity timeout : 62
 Number of groups : 1
  Group: 226.2.3.2

AMT message count:
AMT Request    AMT membership update
2              2

 AMT gateway address : 11.11.11.3, port : 2268
 AMT tunnel interface : ud-5/2/10.1120513
 AMT tunnel state : Active
 AMT tunnel inactivity timeout : 214
 Number of groups : 1
  Group: 226.2.3.3

AMT message count:
AMT Request    AMT membership update
2              2
```

show amt tunnel tunnel-interface

```
user@host> show amt tunnel tunnel-interface ud-5/3/10.1120512
 AMT gateway address : 11.11.11.2, port : 2268
 AMT tunnel interface : ud-5/3/10.1120512
 AMT tunnel state : Active
 AMT tunnel inactivity timeout : 145
 Number of groups : 1

AMT message count:
AMT Request    AMT membership update
2              2
```

show amt tunnel gateway-address

```
user@host> show amt tunnel gateway-address 11.11.11.3 port 2268
AMT gateway address : 11.11.11.3, port : 2268
 AMT tunnel interface : ud-5/2/10.1120513
 AMT tunnel state : Active
 AMT tunnel inactivity timeout : 214
 Number of groups : 1
  Group: 226.2.3.3

AMT message count:
AMT Request    AMT membership update
2              2
```

show amt tunnel gateway-address detail

```
user@host> show amt tunnel gateway-address 11.11.11.2 detail
AMT gateway address : 11.11.11.2, port : 2268
 AMT tunnel interface : ud-5/3/10.1120512
 AMT tunnel state : Active
 AMT tunnel inactivity timeout : 234
 Number of groups : 1
  Group: 226.2.3.2

AMT message count:
```

```
AMT Request     AMT membership update
2               2
```

Release Information

Command introduced in Junos OS Release 10.2.

Output Fields

Table 154 on page 17045 lists the output fields for the `command-name` command. Output fields are listed in the approximate order in which they appear.

Table 154: show analyzer Output Fields

Field Name	Field Description
Analyzer name	Displays the name of the analyzer.
Output interface	Specifies a local interface to which mirrored packets are sent. An analyzer can have output to either an interface or a VLAN, not both.
Output VLAN	Specifies a VLAN to which mirrored packets are sent. An analyzer can have output to either an interface or a VLAN, not both.
Mirror ratio	Displays the ratio of packets to be mirrored.
Egress monitored interfaces	Displays interfaces for which traffic exiting the interfaces is mirrored.
Ingress monitored interfaces	Displays interfaces for which traffic entering the interfaces is mirrored.
Ingress monitored VLANs	Displays VLANs for which traffic entering the VLAN is mirrored.

Sample Output

show analyzer

```
user@host> show analyzer
Analyzer name           : employee-monitor
  Output interface             : ge-0/0/10.0
  Output VLAN                  : remote-analyzer
  Mirror ratio                 : 1
  Loss priority                : High
  Egress monitored interfaces  : ge-0/0/3.0
  Ingress monitored interfaces : ge-0/0/0.0
  Ingress monitored interfaces : ge-0/0/1.0
```

Release Information

Command introduced in Junos OS Release 9.0.

Output Fields

Table 155 on page 17047 lists the output fields for the `show ancp cos` command. Output fields are listed in the approximate order in which they appear.

Table 155: show ancp cos Output Fields

Field Name	Field Description
`Per-DSL CoS adjustment`	Adjustment values applied by the ANCP agent to the actual downstream rates and frame overhead for frame-mode DSL types. The agent then reports the adjusted rates to CoS to establish a shaping rate for the CoS node that corresponds to the subscriber access line.

Table 155: show ancp cos Output Fields *(Continued)*

Field Name	Field Description
`QoS Adjust Flag`	State of QoS adjust: • `TRUE`—The ANCP agent is enabled to adjust the actual downstream data rates and frame overhead and report the adjusted values to CoS. • `FALSE`—The ANCP agent is not enabled to adjust and report values to CoS.
`ADSL bytes`	Number of bytes by which the actual ADSL downstream cell overhead is adjusted before reporting it to CoS.
`ADSL2 bytes`	Number of bytes by which the actual ADSL2 downstream cell overhead is adjusted before reporting it to CoS.
`ADSL2-PLUS bytes`	Number of bytes by which the actual ADSL2+ downstream cell overhead is adjusted before reporting it to CoS.
`SDSL overhead adjusted`	Percentage by which the actual SDSL downstream rate is adjusted before reporting it to CoS.
`SDSL bytes`	Number of bytes by which the actual SDSL downstream frame overhead is adjusted before reporting it to CoS.
`OTHER overhead adjusted`	Percentage by which the actual OTHER downstream rate is adjusted before reporting it to CoS.
`OTHER bytes`	Number of bytes by which the actual OTHER downstream frame overhead is adjusted before reporting it to CoS.
`VDSL overhead adjusted`	Percentage by which the actual VDSL downstream rate is adjusted before reporting it to CoS.
`VDSL bytes`	Number of bytes by which the actual VDSL downstream frame overhead is adjusted before reporting it to CoS.

Table 155: show ancp cos Output Fields *(Continued)*

Field Name	Field Description
VDSL2 overhead adjusted	Percentage by which the actual VDSL2 downstream rate is adjusted before reporting it to CoS.
VDSL2 bytes	Number of bytes by which the actual VDSL2 downstream frame overhead is adjusted before reporting it to CoS.
Per-DSL adjustment for reporting	Adjustment values applied by the ANCP agent to the actual downstream rates for individual DSL types to account for traffic overhead. The agent then reports the adjusted rates to AAA.
ADSL adjustment factor	Percentage by which the actual ADSL downstream rate is adjusted before reporting it to AAA.
ADSL2 adjustment factor	Percentage by which the actual ADSL2 downstream rate is adjusted before reporting it to AAA.
ADSL2+ adjustment factor	Percentage by which the actual ADSL2+ downstream rate is adjusted before reporting it to AAA.
VDSL adjustment factor	Percentage by which the actual VDSL downstream rate is adjusted before reporting it to AAA.
VDSL2 adjustment factor	Percentage by which the actual VDSL2 downstream rate is adjusted before reporting it to AAA.
SDSL adjustment factor	Percentage by which the actual SDSL downstream rate is adjusted before reporting it to AAA.
OTHER adjustment factor	Percentage by which the actual OTHER downstream rate is adjusted before reporting it to AAA.
Keepalive Timer	Interval between the keepalive messages that the ANCP agent sends to CoS.

Table 155: show ancp cos Output Fields *(Continued)*

Field Name	Field Description
`Cos State`	State of the interaction between the ANCP agent and CoS: • ANCPD_COS_CONNECT_NEEDED • ANCPD_COS_CONNECT_PENDING • ANCPD_COS_CONNECT_DONE • ANCPD_COS_SESSION_SENT • ANCPD_COS_WRITE_READY
`Connect Time`	Time at which the ANCP agent connected to CoS; useful for debugging.
`Session Time`	Time at which the ANCP agent sent a session connect message to CoS; useful for debugging.
`Routing Instance Time`	Time at which the ANCP agent sent the routing instance to CoS; useful for debugging.
`Keepalive Time`	Time at which the last keepalive message was sent.
`Update Time`	Time at which the shaping rate was last updated.
`Type`	Subscriber access type: `ifl` indicates that a single VLAN carries subscriber traffic and `iflset` indicates that a set of VLANs carries subscriber traffic.
`Name`	System-wide name of the particular subscriber access.
`Index`	Access identifier.
`Pending Update`	Actual downstream data rate to be applied next to this local loop, in Kbps.
`Last Update`	Adjusted downstream data rate last reported to CoS by the ANCP agent for this local loop, in Kbps.

Sample Output

show ancp cos

```
user@host> show ancp cos

Per-DSL CoS adjustment:
  Qos Adjust Flag:         TRUE
  ADSL bytes:              20
  ADSL2 bytes:              20

Output Fields

Table 156 on page 17055 lists the output fields for the `show ancp neighbor` command. Output fields are listed in the approximate order in which they appear.

Table 156: show ancp neighbor Output Fields

Field Name	Field Description	Level of Output
Version	Version of the ANCP implementation: • `0x31`—General Switch Management Protocol (GSMP) version 3, sub-version 1; ANCP version before *RFC 6320, Protocol for Access Node Control Mechanism in Broadband Networks*. • `0x32`—ANCP version 1, defined in *RFC 6320, Protocol for Access Node Control Mechanism in Broadband Networks*.	`brief` `detail` none
`IP Address`	IP address of the ANCP neighbor.	`brief` `detail` none
`PartId`	Number that associates the ANCP message with a specific partition.	`brief` none

Table 156: show ancp neighbor Output Fields *(Continued)*

Field Name	Field Description	Level of Output
State	Operational state of the ANCP adjacency: • Configured—The neighbor has been configured, but has never been in the Established state. An asterisk (*) is prefixed to the neighbor entry for this state. • Establishing—Adjacency negotiations are in progress for the neighbor. An asterisk (*) is prefixed to the neighbor entry for this state. This state is rarely seen because the adjacency is established so quickly. • Established—Adjacency negotiations have succeeded for the neighbor and an ANCP session has been established. • Not Estblshed—Not Established; adjacency negotiations are ready to begin. Indicates that this neighbor previously had been in the Established state; that is, it has lost a previously established adjacency. An asterisk (*) is prefixed to the neighbor entry for this state.	All levels
Time	How long the adjacency has been up in one of the following formats: • *nwndnh*—number of weeks, days, and hours • *nd hh:mm:ss*—number of days, hours, minutes, and seconds	brief detail none
Subscriber Count	Number of subscribers associated with the ANCP neighbor (access local loop).	brief none
Capabilities	Negotiated ANCP capability: • Topo—Topology discovery. • OAM—Performance of local Operations Administration Maintenance (OAM) procedures on an access loop controlled by the router.	All levels
System Name	MAC address of the ANCP neighbor.	detail

Table 156: show ancp neighbor Output Fields *(Continued)*

Field Name	Field Description	Level of Output
`TCP Port`	TCP port on which ANCP messages are exchanged.	`detail`
`System Instance`	Number identifying the ANCP link instance from the edge device's perspective.	`detail`
`Peer Instance`	Number identifying the ANCP instance from the access node's perspective. This number is unique and changes when the node or link comes back up after going down.	`detail`
`Timer`	Adjacency timer value advertised by the ANCP peer in 100 ms increments; the interval between ANCP ACK messages. This value remains constant for the duration of an ANCP session.	`detail`
`Partition Type`	Number that identifies whether partitions are used and how the ID is negotiated: • `0`—No partition. • `1`—Fixed partition requested. • `2`—Fixed partition assigned.	`detail`
`Partition Flag`	Number that specifies the type of partition requested: `1` (new adjacency) or `2` (recovered adjacency).	`detail`
`Partition Identifier`	Number that identifies a logical partition of an access node with which the ANCP agent has formed an adjacency. A value of zero indicates that the agent supports each neighbor on an IP address over a single TCP session with a partition ID of zero. This is the default support case. A nonzero value indicates that the agent supports each neighbor on an IP address over a single TCP session with a nonzero partition ID.	`detail`
`Partition Adjacencies`	Number of adjacencies that share the partition.	`detail`

Table 156: show ancp neighbor Output Fields *(Continued)*

Field Name	Field Description	Level of Output
`Dead Timer`	Remaining period that the edge device waits for adjacency packets from a neighbor before declaring the neighbor to be down. The maximum dead time value is three times the configured adjacency timer value. This field displays the current value based on the time that the last adjacency packet was received.	`detail`
`Received Syn Count`	Number of synchronization messages received from neighbors to maintain adjacencies.	`detail`
`Received Synack Count`	Number of synchronization acknowledgment messages received from neighbors in response to the node's synchronization messages.	`detail`
`Received Rstack Count`	Number of messages received from neighbors indicating that the link to the neighbor needs to be reset.	`detail`
`Received Ack Count`	Number of acknowledgment messages periodically received from neighbors after an adjacency has been established.	`detail`
`Received Port Up Count`	Number of status messages received from neighbors indicating that a port has transitioned to the up state.	`detail`
`Received Port Down Count`	Number of status messages received from neighbors indicating that a port has transitioned to the down state.	`detail`
`Received Generic Resp Count`	Number of generic response messages received from neighbors.	`detail`
`Received Adjacency Update Count`	Number of adjacency update messages received from neighbors.	`detail`
`Received OAM Count`	Number of OAM responses received from neighbors in reply to `request` commands.	`detail`

Table 156: show ancp neighbor Output Fields *(Continued)*

Field Name	Field Description	Level of Output
`Received Other Count`	Number of all other ANCP message packets received from neighbors that do not fit into one of the other categories.	`detail`
`Sent Syn Count`	Number of synchronization messages sent to neighbors to maintain adjacencies.	`detail`
`Sent Synack Count`	Number of synchronization acknowledgment messages sent to neighbors in response to the their synchronization messages.	`detail`
`Sent Rstack Count`	Number of messages sent to neighbors indicating that the link to the neighbor needs to be reset.	`detail`
`Sent Ack Count`	Number of acknowledgment messages periodically sent to neighbors after an adjacency has been established.	`detail`
`Sent Generic Resp Count`	Number of generic response messages sent to neighbors.	`detail`
`Sent OAM Count`	Number of OAM `request` commands sent to neighbors.	`detail`
`Max Discovery Limit Exceed Count`	Number of times that the maximum number of discovery table entries accepted from the neighbor has been exceeded.	`detail`

Table 156: show ancp neighbor Output Fields *(Continued)*

Field Name	Field Description	Level of Output
Additional Counters • `Internal Port Up Sent Count` • `Internal Port Down Sent Count` • `Internal Port Reset Count` • `Internal Adjacency Loss Port Down Count` • `Internal Access Change Port Down Count` • `Adjacency Loss Timeout Count`	• Port-up count sent due to protocol triggered port-ups. • Port-down count sent due to protocol triggered port-downs. • Port reset count (which is port down and up) on issue of 'clear ancp access-loop' command. • Port-down count due to adjacency loss. • Count of adjacency losses occurred for neighbor. • Timestamp of sent and received at GSMP stack. • Timestamp of adjacency loss and EOF (end of file / TCP FIN) received from the neighbor. • Count of EOFs received from neighbor.	`detail`

Table 156: show ancp neighbor Output Fields *(Continued)*

Field Name	Field Description	Level of Output
`Result Codes`	Number of generic response messages sent to neighbors that include each of the following result codes: • `Invalid Request Message Count`—A properly formed request message violated the protocol because of timing (such as a race condition) or direction of transmission. • `Specified Port(s) Down Count`—One or more of the specified ports are down because of a state mismatch between the router and an ANCP control application. • `Out of Resources Count`—ANCP is out of resources, probably not related to the access lines. This result code is sent only by an access node. • `Request Msg Not Implemented Count`— • `Malformed Msg Count`—Message is malformed because it was corrupted in transit or there was an implementation error at either end of the connection. • `TLV Missing Count`—One or more mandatory TLVs was missing from a request. • `Invalid TLV Contents Count`—The contents of one or more TLVs in the request do not match its required specification. • `Non-Existent Port(s) Count`—One or more of the ports specified in a request do not exist, possibly because of a configuration mismatch between the access node and the router or AAA.	`detail`

Sample Output

show ancp neighbor

```
user@host> show ancp neighbor
  Version IP Address       PartID  State         Time        Subscriber    Capabilities

```

Release Information

Command introduced in Junos OS Release 9.4.

Additional counters added starting Junos OS Release 21.2R1.

Syntax

```
show ancp statistics
<ip-address ip-address>
<system-name mac-address>
```

Description

Display statistics for all ANCP neighbors (access nodes) or the specified ANCP neighbor.

Options

none	Display statistics for all ANCP neighbors, including global statistics not show for individual neighbors.
ip-address *ip-address*	(Optional) Display statistics for only the neighbor with the specified IP address.

system-name ***mac-address***	(Optional) Display statistics for only the neighbor with the specified MAC address.

Required Privilege Level

Output Fields

Table 157 on page 17067 lists the output fields for the `show ancp statistics` command. Output fields are listed in the approximate order in which they appear.

Table 157: show ancp statistics Output Fields

Field Name	Field Description
`Number of neighbors`	Total count of ANCP neighbors.
`Number of subscribers`	Total count of ANCP subscribers.
`Accept Count`	Number of neighbor TCP/IP sessions accepted on listener socket.
`Accept Fail Count`	Number of neighbor TCP/IP sessions that failed due to one of the following causes: session already exists, maximum number of ANCP connections exceeded, creation of session or neighbor failed, or protocol start failed.
`No Config Accept Deny Count`	Number of neighbor TCP/IP sessions that failed because the neighbor was not configured.
`Received Syn Count`	Number of synchronization messages received from neighbors to maintain adjacencies.
`Received Synack Count`	Number of synchronization acknowledgment messages received from neighbors in response to the node's synchronization messages.
`Received Rstack Count`	Number of messages received from neighbors indicating that the link to the neighbor needs to be reset.

Table 157: show ancp statistics Output Fields *(Continued)*

Field Name	Field Description
`Received Ack Count`	Number of acknowledgment messages periodically received from neighbors after an adjacency has been established.
`Received Port Up Count`	Number of status messages received from neighbors indicating that a port has transitioned to the up state.
`Received Port Down Count`	Number of status messages received from neighbors indicating that a port has transitioned to the down state.
`Received Generic Resp Count`	Number of generic response messages received from neighbors.
`Received Adjacency Update Count`	Number of adjacency update messages received from neighbors.
`Received OAM Count`	Number of OAM responses received from neighbors in reply to `request` commands.
`Received Other Count`	Number of all other ANCP message packets received from neighbors that do not fit into one of the other categories.
`Sent Syn Count`	Number of synchronization messages sent to neighbors to maintain adjacencies.
`Sent Synack Count`	Number of synchronization acknowledgment messages sent to neighbors in response to the their synchronization messages.
`Sent Rstack Count`	Number of messages sent to neighbors indicating that the link to the neighbor needs to be reset.
`Sent Ack Count`	Number of acknowledgment messages periodically sent to neighbors after an adjacency has been established.

Table 157: show ancp statistics Output Fields *(Continued)*

Field Name	Field Description
`Sent Generic Resp Count`	Number of generic response messages sent to neighbors.
`Sent OAM Count`	Number of OAM `request` commands sent to neighbors.
`Result Codes`	Number of generic response messages sent to neighbors that include each of the following result codes: • `Invalid Request Message Count`—A properly formed request messages violated the protocol because of timing (such as a race condition) or direction of transmission. • `Specified Port(s) Down Count`—One or more of the specified ports are down because of a state mismatch between the router and an ANCP control application. • `Out of Resources Count`—the ANCP agent is out of resources, probably not related to the access lines. This result code is sent only by an access node. • `Request Msg Not Implemented Count`— • `Malformed Msg Count`—Message is malformed because it was corrupted in transit or there was an implementation error at either end of the connection. • `TLV Missing Count`—One or more mandatory TLVs was missing from a request. • `Invalid TLV Contents Count`—The contents of one or more TLVs in the request do not match its required specification. • `Non-Existent Port(s) Count`—One or more of the ports specified in a request do not exist, possibly because of a configuration mismatch between the access node and the router or AAA.

Sample Output

show ancp statistics

```
user@root> show ancp statistics
  Statistics
    Number of neighbors             : 0
```

```

Syntax

```
show ancp subscriber
<brief | detail>
<access-aggregation-circuit-id circuit-identifier>
<identifier identifier>
<ip-address ip-address>
<system-name mac-address>
```

Description

Display information about active subscribers regardless of the subscriber's operational state, for all subscribers (local access loops), the subscriber associated with the access line specified by an ACI, or the subscriber associated with the specified ANCP neighbor (access node).

After an ancpd restart, this command displays orphaned entries (marked with an o) for subscriber sessions that were established before the restart but which have not yet been reestablished. As sessions are reestablished, the number of orphaned entries displayed by the command decreases. The number reaches zero when all sessions are reestablished or when the orphaned-interface timer expires.

Options

none	Display information about all subscribers.
brief | detail	(Optional) Display the specified level of detail.
access-aggregation-circuit-id *circuit-identifier*	(Optional) Display information about ANCP subscribers whose Access-Aggregation-Circuit-ID-ASCII attribute (TLV 0x0003) matches the specified value. A *circuit-identifier* that begins with the# character indicates a backhaul line identifier. You can specify a wildcard (*) anywhere in the string.
identifier *identifier*	(Optional) Display information about the subscriber associated with the access line (ACI) specified by the access identifier.

ip-address *ip-address* (Optional) Display information about the subscribers connected to the access node specified by the IP address.

system-name *mac-address* (Optional) Display information about the subscribers connected to the access node specified by the MAC address.

Required Privilege Level

Output Fields

Table 158 on page 17074 lists the output fields for the `show ancp subscriber` command. Output fields are listed in the approximate order in which they appear.

Table 158: show ancp subscriber Output Fields

Field Name	Field Description	Level of Output
`Loop Identifier`	Access loop identifier as sent by the access node and configured to map the subscriber to an interface. An asterisk (*) indicates that the information might be stale due to receiving a Port Down message with a DSL Line State of Idle. Two asterisks (**) indicate that the neighbor associated with the subscriber has lost its adjacency. In this case, the DSL Line State might be Established. An `o` indicates that the entry is for an orphaned interface and represents a previously established subscriber session that has not been reestablished after an ancpd restart. The number of orphaned entries decreases as the ANCP neighbors reestablish adjacencies and the protocol subscriber sessions are reestablished. The command output indicates this by removing the `o` marker. Eventually the number of orphaned entries reaches zero, because either all the adjacencies and subscriber sessions have been reestablished or any remaining orphaned entries are removed when the orphaned-interface timer expires.	`brief` none

Table 158: show ancp subscriber Output Fields *(Continued)*

Field Name	Field Description	Level of Output
DSL Line State	State of the DSL line: Idle, Showtime, or Silent.	brief detail
Access Type	Type of access line employed by the access node: ADSL1, ADSL2, ADSL2+, VDSL1, VDSL2, SDSL, G.fast, VDSL2 Annex Q, SDSL bonded, VDSL2 bonded, G.fast bonded VDSL2 Annex Q bonded or OTHER.	brief detail none
Interface	Name of the interface set or logical interface.	brief detail none
Rate Kbps	Actual downstream data rate for this local loop.	brief none
Neighbor	IP address of ANCP neighbor (access node).	brief none
Access Loop Circuit Identifier	Access loop circuit identifier as sent by the access node and configured to map the subscriber to an interface. An asterisk (*) indicates that the information might be stale due to receiving a Port Down message with a DSL Line State of Idle. Two asterisks (**) indicate that the neighbor associated with the subscriber has lost its adjacency. In this case, the DSL Line State might be Established.	detail
Neighbor IP Address	IP address of the ANCP neighbor (access node).	detail
Aggregate Circuit Identifier	ASCII identifier for the subscriber access loop; value of the Access-Aggregation-Circuit-ID-ASCII attribute (TLV 0x0003).	detail
Aggregate Circuit Identifier Binary	Binary identifier for the VLAN circuit ID.	detail
Tech Type	Type of technology employed by the subscriber. Currently Junos OS supports DSL technology type only.	detail

Table 158: show ancp subscriber Output Fields *(Continued)*

Field Name	Field Description	Level of Output
`DSL Line Data Link`	Data link protocol employed on the access loop: `AAL5` or `Ethernet`.	`detail`
`DSL Line Encapsulation`	Encapsulation type on the access loop, for Ethernet only: • `0`—NA, type not conveyed • `1`—Untagged Ethernet • `2`—Single-tagged Ethernet	`detail`
`DSL Line Encapsulation Payload`	Payload carried across the access loop: • `0`—NA, type not conveyed • `1`—PPPoA LLC • `2`—PPPoA null • `3`—IPoA LLC • `4`—IPoA null • `5`—Ethernet over AAL5 LLC with FCS • `6`—Ethernet over AAL5 LLC without FCS • `7`—Ethernet over AAL5 null with FCS • `8`—Ethernet over AAL5 null without FCS	`detail`
`Interface Type`	Type of interface employed for subscriber traffic: `ifl` for a single VLAN or `interface-set` for a configured group of VLANs.	`detail`
`Actual Net Data Upstream`	Actual upstream data rate for this local loop, in Kbps.	`detail`

Table 158: show ancp subscriber Output Fields *(Continued)*

Field Name	Field Description	Level of Output
`Actual Net Data Downstream`	Actual downstream data rate for this local loop, in Kbps.	`detail`
`Minimum Net Data Upstream`	Minimum upstream data rate desired by the operator for this local loop, in Kbps.	`detail`
`Minimum Net Data Downstream`	Minimum downstream data rate desired by the operator for this local loop, in Kbps.	`detail`
`Maximum Net Data Upstream`	Maximum upstream data rate desired by the operator for this local loop, in Kbps.	`detail`
`Maximum Net Data Downstream`	Maximum downstream data rate desired by the operator for this local loop, in Kbps.	`detail`
`Attainable Net Data Upstream`	Maximum attainable upstream data rate for this local loop, in Kbps.	`detail`
`Attainable Net Data Downstream`	Maximum attainable downstream data rate for this local loop, in Kbps.	`detail`
`Minimum Low Power Data Downstream`	Minimum downstream data rate desired by the operator for this local loop in low power state, in Kbps.	`detail`
`Minimum Low Power Data Upstream`	Minimum upstream data rate desired by the operator for this local loop in low power state, in Kbps.	`detail`
`Maximum Interleave Delay Downstream`	Maximum interleaving delay for downstream data, in milliseconds.	`detail`
`Maximum Interleave Delay Upstream`	Maximum interleaving delay for upstream data, in milliseconds.	`detail`

Table 158: show ancp subscriber Output Fields *(Continued)*

Field Name	Field Description	Level of Output
Actual Interleave Delay Downstream	Actual interleaving delay for downstream data, in milliseconds.	detail
Actual Interleave Delay Upstream	Actual interleaving delay for upstream data, in milliseconds.	detail
Port-Up Timestamp	Timestamp when port comes up or port enabled.	detail
Port Down Timestamp	Timestamp when port goes down or disabled.	detail
Port Down Event	Reason for port to be disabled.	detail

Release Information

Command introduced in Junos OS Release 9.4.

`neighbor` option replaced with `ip-address` in Junos OS Release 16.1.

`system-name` option introduced in Junos OS Release 16.1.

`access-aggregation-circuit-id` option introduced in Junos OS Release 18.4R1.

Output Fields

Table 159 on page 17084 lists the output fields for the `show ancp summary` command. Output fields are listed in the approximate order in which they appear.

Table 159: show ancp summary Output Fields

Field Name	Field Description
`Configured`	Number of ANCP neighbors in the `Configured` state; that is, that have been configured but never established.
`Establishing`	Number of ANCP neighbors in the `Establishing` state; that is, where negotiations are in progress.
`Established`	Number of ANCP neighbors in the `Established` state; that is, where negotiations have succeeded and the ANCP session has been established.
`Not Estblshd`	Number of ANCP neighbors in the `Not Estblshd` state; that is, that have lost a previously established adjacency and are ready to begin negotiations.
`Total`	Total number of ANCP neighbors; sum of neighbors in the `Configured`, `Establishing`, `Established`, and `Not Estblshd` states.
`Showtime`	Number of DSL lines in `Showtime` state.
`Idle`	Number of DSL lines in `Idle` state.
`Silent`	Number of DSL lines in `Silent` state.
`Unknown`	Number of DSL lines where the state is not `Showtime`, `Idle`, or `Silent`.

Table 159: show ancp summary Output Fields *(Continued)*

Field Name	Field Description
Total	Total number of DSL lines (ANCP subscribers); sum of DSL lines in the Showtime, Idle, Silent, and Unknown states.

Sample Output

show ancp summary

```
user@host> show ancp summary

Neighbors Summary:
  Configured  Establishing  Established  Not Established     Total
  ----------  ------------  -----------  ---------------  ----------
          22             0            2                0          24

Subscribers Summary:
  Showtime      Idle      Silent     Unknown     Total
  ---------- ---------- ----------- ---------- ----------
           4          0           0          0          4
```

Release Information

Command introduced in Junos OS Release 13.1.

show ancp summary neighbor

IN THIS SECTION

- Syntax | 17086
- Description | 17086
- Options | 17086
- Required Privilege Level | 17086
- Output Fields | 17087
- Sample Output | 17088
- Release Information | 17088

Syntax

```
show ancp summary neighbor
<ip-address ip-address | system-name mac-address>
```

Description

Display a summary of the counts and states for all ANCP neighbors and of the neighbor's subscribers when you specify a particular neighbor.

Options

ip-address *ip-address*	(Optional) IP address of the ANCP neighbor (access node).
system-name *mac-address*	(Optional) MAC address of the ANCP neighbor (access node).

Output Fields

Table 160 on page 17087 lists the output fields for the `show ancp summary` command. Output fields are listed in the approximate order in which they appear.

Table 160: show ancp summary neighbor Output Fields

Field Name	Field Description
`Configured`	Number of ANCP neighbors in the `Configured` state; that is, that have been configured but never established.
`Establishing`	Number of ANCP neighbors in the `Establishing` state; that is, where negotiations are in progress.
`Established`	Number of ANCP neighbors in the `Established` state; that is, where negotiations have succeeded and the ANCP session has been established.
`Not Estblshd`	Number of ANCP neighbors in the `Not Estblshd` state; that is, that have lost a previously established adjacency and are ready to begin negotiations.
`Total`	Total number of ANCP neighbors; sum of neighbors in the `Configured`, `Establishing`, `Established`, and `Not Estblshd` states.
`Showtime`	Number of DSL lines for the neighbor in `Showtime` state.
`Idle`	Number of DSL lines for the neighbor in `Idle` state.
`Silent`	Number of DSL lines for the neighbor in `Silent` state.
`Unknown`	Number of DSL lines for the neighbor where the state is not `Showtime`, `Idle`, or `Silent`.
`Total`	Total number of DSL lines (ANCP subscribers); sum of DSL lines in the `Showtime`, `Idle`, `Silent`, and `Unknown` states.

Sample Output

show ancp summary neighbor

```
user@host> show ancp summary neighbor

Neighbors Summary:
  Configured  Establishing  Established  Not Established     Total
  ----------  ------------  -----------  ---------------  ----------
          22             0            2                0          24
```

show ancp summary neighbor (IP Address)

```
user@host> show ancp summary neighbor ip-address 192.168.10.1

Neighbor Summary:192.168.10.1 status Established

Subscribers Summary:
  Show Time     Idle      Silent     Unknown     Total
  ---------- ---------- ----------- ---------- ----------
           6          0           0          0          6
```

show ancp summary neighbor (MAC Address)

```
user@host> show ancp summary neighbor system-name 00:00:5E:00:53:02

Neighbor Summary:00:00:5E:00:53:02 status Established

Subscribers Summary:
  Show Time     Idle      Silent     Unknown     Total
  ---------- ---------- ----------- ---------- ----------
           5          1           2          0          8
```

Release Information

Command introduced in Junos OS Release 13.1.

show app-engine crash

IN THIS SECTION

- Syntax | 17091
- Description | 17091
- Options | 17092
- Additional Information | 17092
- Required Privilege Level | 17092
- Output Fields | 17092
- Sample Output | 17093
- Release Information | 17093

Syntax

```
show app-engine crash
<compute-cluster compute-cluster-name>
<compute-cluster compute-cluster-name compute-node compute-node-name>
```

Description

Displays information regarding crashes on the Junos V App Engine or host OS. The command displays the list of files present in the **/var/crash/** directory, as well as some core files located in the **/var/tmp/** directory.

Options

- `compute-cluster` *`compute-cluster-name`* `compute-node` *`compute-node-name`*—Name of the compute cluster and compute node. On QFX switches with a host OS, the default compute cluster and compute node names are default-cluster and default-node, and the command applies to the host OS by default.

Additional Information

In the operational mode of the CLI when you type **?** for a name, for example a compute-node name, you would expect to get a list of available compute nodes plus the option to type in a name not listed. This is the auto-complete feature in the CLI. However, in JunosV App Engine, ,if you specify compute cluster and compute node in the operational command, the auto-complete works only if the compute cluster is put before the compute node.

For commands with an optional `compute-cluster` *`compute-cluster-name`* option, if that option is omitted, the command will be executed on all compute nodes of all compute clusters. For commands with an optional `compute-node` *`compute-node-name`* option, if that option is omitted, the command will be executed on all compute nodes of the specified compute cluster.

Required Privilege Level

view

Output Fields

For a description of the output fields, see Table 162 on page 17092. Output fields are listed in the approximate order in which they appear.

Table 162: show app-engine crash Output Fields

Field Name	Field Description
`Compute Cluster`	Name of compute cluster.
`Compute Node`	Name of compute node.
`Crash Info`	List of core files.

Sample Output

show app-engine crash (QFX5100 Switches)

```
user@host> show app-engine crash

Compute cluster: default-cluster

  Compute node: default-node

   Crash Info
   ==========
   total 0
```

Release Information

Command introduced in Junos OS Release 13.2X51-D15.

Release Information | **17096**

Syntax

```
show app-engine logs
<compute-cluster compute-cluster-name>
<compute-cluster compute-cluster-name compute-node compute-node-name>
```

Description

Displays log files regarding the state of the specified Guest VM or host OS, located in the **/var/log/** directory.

Options

- `compute-cluster` *`compute-cluster-name`* `compute-node` *`compute-node-name`*—Name of the compute cluster and name of the compute node. On QFX switches with a host OS, the default compute cluster and compute node names are default-cluster and default-node, and the command applies to the host OS by default.

Additional Information

In the operational mode of the CLI when you type **?** for a name, for example a compute-node name, you would expect to get a list of available compute nodes plus the option to type in a name not listed. This is the auto-complete feature in the CLI. However, in JunosV App Engine, if you specify compute cluster and compute node in the operational command, the auto-complete works only if the compute cluster is put before the compute node.

For commands with an optional `compute-cluster` *`compute-cluster-name`* option, if that option is omitted, the command will be executed on all compute nodes of all compute clusters. For commands with an optional `compute-node` *`compute-node-name`* option, if that option is omitted, the command will be executed on all compute nodes of the specified compute cluster.

show arp

IN THIS SECTION

- Syntax | 17097
- Description | 17097
- Options | 17098
- Required Privilege Level | 17099
- Output Fields | 17099
- Sample Output | 17100
- Release Information | 17102

Syntax

```
show arp
<expiration-time>
<hostname host-name>
<interface interface-name>
<logical-system logical-system-name>
<no-resolve>
<reference-count count>
<tenant name>
<state state>
<vpn vpn-name>
```

Description

Display all entries in the Address Resolution Protocol (ARP) table. To display entries for a particular logical system only, first enter the `set cli logical-system` *`logical-system-name`* command, and then enter the `show arp` command.

To force the output of this command to show the IP address by the hostname of each device, also configure the `force-show-arp-resolve` statement at the `[edit system services subscriber-management overrides]` hierarchy.

NOTE: Starting with Junos OS Release 14.2, the following enhancements have been made to the output of the `show arp interfaces` command:

- For integrated routing and bridging (IRB) interfaces, in the output of the `show arp` command, the IRB interface name is displayed under the Interface field of the output and the Layer 2 interface identifier is specified in square brackets following the IRB name. Until Release 14.1 and earlier, only the layer 2 interface name and not the IRB name was displayed.

- Starting with release 14.2, if you do not specify a subinterface or a logical unit of the interface with the `show arp interface` *`interface-name`* command, an error message is shown. Until Release 14.1 and earlier, if you did not specify the subinterface for a physical interface, the system considered the supplied command to be for subinterface 0 and displayed the output. For example, if you entered ge-2/2/5, it was processed by the system as ge-2/2/5.0.

- When IRB interfaces are configured and if you attempt to specify an interface name that is not configured on the system, an error message is displayed stating the particular interface is not defined on the system. Until release 14.1 and earlier, unrelated and incorrect entries were displayed even for interface names that did not exist.
- Starting with Release 14.2, you can enter the `show arp interface` command with the IRB name and retrieve the statistical details for the IRB interface. This functionality was not available previously. However, you could previously obtain the ARP details of an IRB interface that had a Layer 2 interface configured.

NOTE: Starting with Junos OS Release 16.1, `show arp no-resolve` command does not display the underlying ifl information if `enhanced-convergence` statement at `[edit irb unit unit-number]` hierarchy level and `enhanced-ip` statement at [edit chassis network-services] hierarchy level is configured for the destination interface IRB.

Options

none	Display the entries in the ARP table.
expiration-time	(Optional) Display the amount of time, in seconds, until each ARP entry is set to expire.
hostname *host-name*	(Optional) Display the hostname.
interface *interface-name*	(Optional) Display information about ARP for the specified logical interface
logical-system *logical-system-name*	(Optional) Display ARP entries for the specified logical system; only available on the main router context.
no-resolve	(Optional) Do not attempt to determine the hostname that corresponds to the IP address.
reference-count *count*	(Optional) Display the next-hop reference count.
state *state*	(Optional) Display the next-hop current state.
tenant *name*	(Optional) Display the ARP entries for the specified tenant. Only available in the main router context.

vpn *vpn-name* (Optional) Display entries in the ARP table for the specified virtual private network's (VPN) routing table.

> **NOTE:**
>
> - The `vpn` option displays only entries for non-subscriber interfaces. You must omit this option if you want to view ARP entries for subscriber interfaces.
> - The `show arp vpn` *`vpn-name`* `no-resolve` command does not display entries for subscriber interfaces in the non-default routing-instance, that is when the subscriber interface is coming up in the non-default routing-instance.

Output Fields

Table 164 on page 17099 describes the output fields for the `show arp` command. Output fields are listed in the approximate order in which they appear.

Table 164: show arp Output Fields

Field Name	Field Description
MAC Address	Media access control (MAC) address that corresponds to the IP address.
Address	IP address that corresponds to the hostname.
Name	Hostname.
Interface	Interface name.

Table 164: show arp Output Fields *(Continued)*

Field Name	Field Description
Flags	(`no-resolve` option only) Indicates how mappings between IP and MAC addresses are defined: • `permanent`—Static mapping. The ARP entry never times out. • `published`—The next hop is published. This flag tells the host to respond to ARP request and ARP response packets. When you see this flag, the device acts as an ARP server and responds to host name requests even if the host address is not its own. • `gateway`—The device rewrites the source MAC address with the interface MAC address. You will see this flag when the device uses the interface MAC address for the Layer 2 header. • `remote`—The ARP entry is installed by a process (for example, the l2ald process), not the kernel. • `None`—Dynamic mapping.
TTE	(`expiration-time` option only) Amount of time, in seconds, until ARP entry is set to expire.

Sample Output

show arp

```
user@host> show arp
MAC Address       Address         Name                      Interface
00:e0:81:22:fd:74 192.168.64.10   firewall.my.net           fxp0.0
00:04:5a:65:78:e1 192.168.65.13   lab.my net                fxp0.0
```

show arp no-resolve

```
user@host> show arp no-resolve
MAC Address       Address         Interface     Flags
00:90:69:96:00:01 10.10.45.5      fe-0/0/1.0    none
00:00:00:00:00:01 200.200.200.1   fe-0/0/0.0    permanent published
00:00:00:00:00:02 200.200.200.2   fe-0/0/0.0    permanent
```

```
00:90:69:91:b0:00 200.200.200.3   fe-0/0/0.0    none
Total entries: 4
```

show arp no-resolve

```
user@host> show arp no-resolve (QFX Series)
```

The command is displaying the MAC and MAC-IP routes are programmed over the .local interface.

Output Fields

Table 165 on page 17104 lists the output fields for the `show arp inspection statistics` command. Output fields are listed in the approximate order in which they appear.

Table 165: show arp inspection statistics Output Fields

Field Name	Field Description	Level of Output
Interface	Interface on which ARP inspection has been applied.	All levels
Packets received	Total number of packets total that underwent ARP inspection.	All levels
ARP inspection pass	Total number of packets that passed ARP inspection.	All levels
ARP inspection failed	Total number of packets that failed ARP inspection.	All levels

Sample Output

show arp inspection statistics

```
user@switch> show arp inspection statistics

Interface     Packets received     ARP inspection pass  ARP inspection failed
---------     -----------------    -------------------  ---------------------
  ge-0/0/0                    0                      0                      0
  ge-0/0/1                    0                      0                      0
  ge-0/0/2                    0                      0                      0
  ge-0/0/3                    0                      0                      0
  ge-0/0/4                    0                      0                      0
  ge-0/0/5                    0                      0                      0
  ge-0/0/6                    0                      0                      0
  ge-0/0/7                  703                    701                      2
```

Release Information

Command introduced in Junos OS Release 9.0.

Syntax

```
show as-path
<brief | detail>
<logical-system (all | logical-system-name)>
```

Syntax (EX Series Switches)

```
show as-path
<brief | detail>
```

Description

Display the distribution of autonomous system (AS) paths that the local routing device is using (usually through the routing table). Use this command to debug problems for AS paths and to understand how AS paths have been manipulated through a policy (through the `as-path-prepend` action) or through aggregation.

AS paths are stored in a hash table. A hash table is one method for fast lookup. Each entry in the table is called a bucket. Junos OS computes a hash value that indicates in which bucket the AS path is stored. The AS paths are dispersed among the hash buckets so that a manageable number of AS paths is stored in each bucket. Only unique AS paths are stored. Duplicate AS paths increase a reference count, but do not increase the number of AS paths stored in the hash table.

Options

none	Display basic information about AS paths that the local routing device is using (same as brief).
brief | detail	(Optional) Display the specified level of output.
logical-system (all | *logical-system-name*)	(Optional) Perform this operation on all logical systems or on a particular logical system.

Output Fields

Table 166 on page 17107 lists the output fields for the `show as-path` command. Output fields are listed in the approximate order in which they appear.

Table 166: show as-path Output Fields

Field Name	Field Description	Level of Output
`Total AS paths`	Total number of AS paths.	`brief` none
`Bucket`	Bucket number.	All levels
`Count`	Number of AS path entries in this bucket.	All levels
`AS path`	AS path through which the route was learned. The letters at the end of the AS path indicate the path origin, providing an indication of the state of the route at the point at which the AS path originated: • `I`—IGP. • `E`—EGP. • `?`—Incomplete; typically, the AS path was aggregated. • `Atomic`—Route is an aggregate of several route prefixes. • `Aggregator`—Routing device has summarized a range of prefixes.	All levels
`domain`	Number of independent AS domains. The AS paths of an independent AS domain are not shared with the AS paths and AS path attributes of other domains, including the master routing instance domain.	`detail`
`neighbor as`	AS peer address.	`detail`
`length`	Length of the AS path.	`detail`
`segments`	Length of the AS segment descriptor.	`detail`
`unique-count`	Number of unique autonomous systems (ASs) present in the AS path	`detail`
`references`	Path reference count.	`detail`

Sample Output
